Preface

Intended Audience

PBS Pro is the professional workload management system from Altair that provides a unified queuing and job management interface to a set of computing resources. This document provides the user with the information required to use the Portable Batch System (PBS), including creating, submitting, and manipulating batch jobs; querying status of jobs, queues, and systems; and otherwise making effective use of the computer resources under the control of PBS.

Related Documents

The following publications contain information that may also be useful to the user of PBS:

PBS-3BQ01   **PBS Pro Quick Start Guide**: offers a short overview of the installation and use of PBS Pro.

PBS-3BA01   **PBS Pro Administrator Guide**: provides the system administrator with information required to install, configure, and manage PBS, as well as a thorough discussion of how the various components of PBS interoperate.

PBS-3BE01   **PBS Pro External Reference Specification**: discusses in detail the PBS application programming interface (API), security within PBS, and intra-daemon communication.

Ordering Software and Publications

To order additional copies of this and other PBS publications, or to purchase additional software licenses, contact an authorized reseller, or the PBS Sales Department. Contact information is included on the copyright page of this document.

Document Conventions

PBS documentation uses the following typographic conventions.

<u>abbr</u>eviation   If a PBS command can be abbreviated (such as sub-commands to qmgr) the shortest acceptable abbreviation is underlined.

`command`   This fixed width font is used to denote literal commands, filenames, error messages, and program output.

`input`   Literal user input is shown in this bold fixed-width font.

`manpage(x)`   Following UNIX tradition, manual page references include the corresponding section number in parentheses appended to the man page name.

terms   Words or terms being defined, as well as variable names, are in italics.

Chapter 1
Introduction

This book, the **User Guide** to the Portable Batch System, Professional Edition (PBS Pro) is intended as your knowledgeable companion to the PBS Pro software. The information herein pertains to PBS in general, with specific information for PBS Pro 5.4.

1.1 Book organization

This book is organized into 9 chapters, plus two appendices. Depending on your intended use of PBS, some chapters will be critical to you, and others may be safely skipped.

Chapter 1   gives an overview of this book, PBS, and the PBS team.

Chapter 2   discusses the various components of PBS and how they interact, followed by definitions of terms used in PBS and in distributed workload management.

Chapter 3   introduces the user to PBS, describing the user interfaces and the user's UNIX environment.

Chapter 4   describes the structure and components of a PBS job, and explains how to create and submit a PBS job.

Chapter 5   introduces the `xpbs` graphical user interface, and shows how to submit a PBS job using `xpbs`.

Chapter 6   describes how to check status of a job, and request status of queues, nodes, systems, or PBS Servers.

Chapter 7   discusses commonly used commands and features of PBS, and explains how to use each one.

Chapter 8   describes and explains how to use the more advanced features of PBS.

Chapter 9   explains how PBS interacts with multi-node and parallel applications, and illustrates how to run such applications under PBS.

Appendix A   provides a quick reference summary of PBS environment variables.

Appendix B   includes information for converting from NQS/NQE to PBS.

1.2 What is PBS Pro?

PBS Pro is the professional version of the Portable Batch System (PBS), a flexible work-load management system, originally developed to manage aerospace computing resources at NASA. PBS has since become the leader in supercomputer workload management and the *de facto* standard on Linux clusters.

Today, growing enterprises often support hundreds of users running thousands of jobs across different types of machines in different geographical locations. In this distributed heterogeneous environment, it can be extremely difficult for administrators to collect detailed, accurate usage data, or to set system-wide resource priorities. As a result, many computing resource are left under-utilized, while other are over-utilized. At the same time, users are confronted with an ever expanding array of operating systems and platforms. Each year, scientists, engineers, designers, and analysts must waste countless hours learning the nuances of different computing environments, rather than being able to focus on their core priorities. PBS Pro addresses these problems for computing-intensive industries such as science, engineering, finance, and entertainment.

Now you can use the power of PBS Pro to better control your computing resources. This allows you to unlock the potential in the valuable assets you already have, while at the

same time, reducing dependency on system administrators and operators, freeing them to focus on other actives. PBS Pro can also help you effectively manage growth by tracking real usage levels across your systems and enhancing effective utilization of future purchases.

1.3 History of PBS

In the past, UNIX systems were used in a completely interactive manner. Background jobs were just processes with their input disconnected from the terminal. However, as UNIX moved onto larger and larger machines, the need to be able to schedule tasks based on available resources increased in importance. The advent of networked compute servers, smaller general systems, and workstations led to the requirement of a networked batch scheduling capability. The first such UNIX-based system was the Network Queueing System (NQS) funded by NASA Ames Research Center in 1986. NQS quickly became the *de facto* standard for batch queueing.

Over time, distributed parallel systems began to emerge, and NQS was inadequate to handle the complex scheduling requirements presented by such systems. In addition, computer system managers wanted greater control over their compute resources, and users wanted a single interface to the systems. In the early 1990's NASA needed a solution to this problem, but found nothing on the market that adequately addressed their needs. So NASA led an international effort to gather requirements for a next-generation resource management system. The requirements and functional specification were later adopted as an IEEE POSIX standard (1003.2d). Next, NASA funded the development of a new resource management system compliant with the standard. Thus the Portable Batch System (PBS) was born.

PBS was quickly adopted on distributed parallel systems and replaced NQS on traditional supercomputers and server systems. Eventually the entire industry evolved toward distributed parallel systems, taking the form of both special purpose and commodity clusters. Managers of such systems found that the capabilities of PBS mapped well onto cluster systems. (For information on converting from NQS to PBS, see Appendix B.)

The PBS story continued when Veridian (the R&D contractor that developed PBS for NASA) released the Portable Batch System Professional Edition (PBS Pro), a commercial, enterprise-ready, workload management solution. Three years later, the Veridian PBS Products business unit was acquired by Altair Engineering, Inc. Altair set up the PBS Products unit as a subsidiary company named Altair Grid Technologies focused on PBS Pro and related Grid software.

1.4 About the PBS Team

The PBS Pro product is being developed by the same team that originally designed PBS for NASA. In addition to the core engineering team, Altair Grid Technologies includes individuals who have supported PBS on computers all around the world, including some of the largest supercomputers in existence. The staff includes internationally-recognized experts in resource- and job-scheduling, supercomputer optimization, message-passing programming, parallel computation, and distributed high-performance computing. In addition, the PBS team includes co-architects of the NASA Metacenter (the first full-production geographically distributed meta-computing grid), co-architects of the Department of Defense MetaQueueing (prototype Grid) Project, co-architects of the NASA Information Power Grid, and co-chair of the Global Grid Forum's Scheduling Group.

1.5 About Altair Engineering

Through engineering, consulting and high performance computing technologies, Altair Engineering increases innovation for more than 1,500 clients around the globe. Founded in 1985, Altair's unparalleled knowledge and expertise in product development and manufacturing extend throughout North America, Europe and Asia. Altair specializes in the development of high-end, open CAE software solutions for modeling, visualization, optimization and process automation.

1.6 Why Use PBS?

PBS Pro provides many features and benefits to both the computer system user and to companies as a whole. A few of the more important features are listed below to give the reader both an indication of the power of PBS, and an overview of the material that will be covered in later chapters in this book.

Enterprise-wide Resource Sharing provides transparent job scheduling on any PBS system by any authorized user. Jobs can be submitted from any client system both local and remote, crossing domains where needed.

Multiple User Interfaces provides a graphical user interface for submitting batch and interactive jobs; querying job, queue, and system status; and monitoring job progress. Also provides a traditional command line interface.

Security and Access Control Lists permit the administrator to allow or deny access to PBS systems on the basis of username, group, host, and/or network domain.

Job Accounting offers detailed logs of system activities for charge-back or usage analysis per user, per group, per project, and per compute host.

Automatic File Staging provides users with the ability to specify any files that need to be copied onto the execution host before the job runs, and any that need to be copied off after the job completes. The job will be scheduled to run only after the required files have been successfully transferred.

Parallel Job Support works with parallel programming libraries such as MPI, PVM and HPF. Applications can be scheduled to run within a single multi-processor computer or across multiple systems.

System Monitoring includes a graphical user interface for system monitoring. Displays node status, job placement, and resource utilization information for both stand-alone systems and clusters.

Job-Interdependency enables the user to define a wide range of inter-dependencies between jobs. Such dependencies include execution order, synchronization, and execution conditioned on the success or failure of another specific job (or set of jobs).

Computational Grid Support provides an enabling technology for meta-computing and computational grids, including support for the Globus Grid Toolkit.

Comprehensive API includes a complete Application Programming Interface (API) for sites who desire to integrate PBS with other applications, or who wish to support unique job scheduling requirements.

Automatic Load-Leveling provides numerous ways to distribute the workload across a cluster of machines, based on hardware configuration, resource availability, keyboard activity, and local scheduling policy.

Distributed Clustering allows customers to utilize physically distributed systems and clusters, even across wide-area networks.

Common User Environment offers users a common view of the job submission, job querying, system status, and job tracking over all systems.

Cross-System Scheduling ensures that jobs do not have to be targeted to a specific computer system. Users may submit their job, and have it run on the first available system that meets their resource requirements.

Job Priority allows users the ability to specify the priority of their jobs; defaults can be provided at both the queue and system level.

Username Mapping provides support for mapping user account names on one system to the appropriate name on remote server systems. This allows PBS to fully function in environments where users do not have a consistent username across all the resources they have access to.

Fully Configurable. PBS was designed to be easily tailored to meet the needs of different sites. Much of this flexibility is due to the unique design of the scheduler module, which permits complete customization.

Broad Platform Availability is achieved through support of Windows 2000 and every major version of UNIX and Linux, from workstations and servers to supercomputers. New platforms are being supported with each new release.

System Integration allows PBS to take advantage of vendor-specific enhancements on different systems (such as supporting "cpusets" on SGI systems).

Chapter 2

Concepts and Terms

PBS is a distributed workload management system. As such, PBS handles the management and monitoring of the computational workload on a set of one or more computers. Modern workload management solutions like PBS Pro include the features of traditional batch queueing but offer greater flexibility and control than first generation batch systems (such as the original UNIX batch system NQS).

Workload management systems have three primary roles:

Queuing   The collecting together of work or tasks to be run on a computer. Users submit tasks or "jobs" to the resource management system where they are queued up until the system is ready to run them.

Scheduling   The process of selecting which jobs to run, when, and where, according to a predetermined policy. Sites balance competing needs and goals on the system(s) to maximize efficient use of resources (both computer time and people time).

Monitoring   The act of tracking and reserving system resources and enforcing usage policy. This covers both user-level and system-level monitoring as well as monitoring of the scheduling policies to see how well they are meeting the stated goals

2.1 PBS Components

PBS consist of two major component types: user-level commands and system daemons. A brief description of each is given here to help you understand how the pieces fit together, and how they affect you.
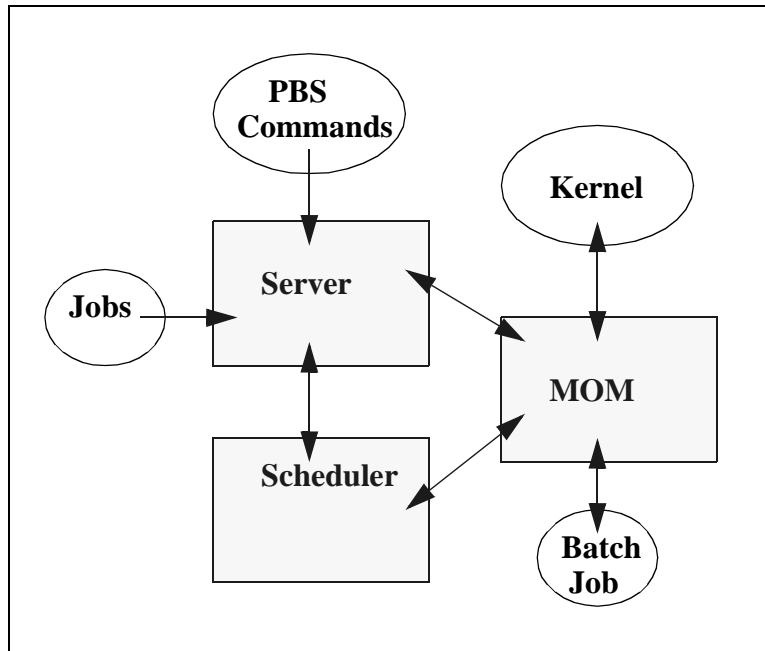

Commands   PBS supplies both UNIX command line programs that are POSIX 1003.2d conforming and a graphical interface. These are used to submit, monitor, modify, and delete jobs. These *client commands* can be installed on any system type supported by PBS and do not require the local presence of any of the other components of PBS.

There are three command classifications: user commands, which any authorized user can use, operator commands, and manager (or administrator) commands. Operator and manager commands which require specific access privileges are discussed in the **PBS Pro Administrator Guide**.

Job Server   The *Job Server* daemon is the central focus for PBS. Within this document, it is generally referred to as *the Server* or by the execution name *pbs_server*. All commands and the other dae-

mons communicate with the Server via an *Internet Protocol* (IP) network. The Server's main function is to provide the basic batch services such as receiving/creating a batch job, modifying the job, protecting the job against system crashes, and running the job. Normally, there is one Server managing a given set of resources. However if the Server Failover feature is enabled, there will be two Servers.

Job Executor (MOM)

The *Job Executor* is the daemon which actually places the job into execution. This daemon, *pbs_mom,* is informally called *MOM* as it is the mother of all executing jobs. (MOM is a reverse-engineered acronym that stands for Machine Oriented Mini-server.) MOM places a job into execution when it receives a copy of the job from a Server. MOM creates a new session that is as identical to a user login session as is possible. For example, if the user's login shell is `csh`, then MOM creates a session in which `.login` is run as well as `.cshrc`. MOM also has the responsibility for returning the job's output to the user when directed to do so by the Server. One MOM daemon runs on each computer which will execute PBS jobs.

A special version of MOM, called the *Globus MOM*, is available if it is enabled during the installation of PBS. It handles submission of jobs to the Globus environment. Globus is a software infrastructure that integrates geographically distributed computational and information resources. Globus is discussed in more detail in the **PBS Pro Administrator Guide**. (To find out if Globus support is enabled at your site, contact your PBS system administrator.)

Job Scheduler

The *Job Scheduler* daemon, *pbs_sched*, implements the site's policy controlling when each job is run and on which resources. The Scheduler communicates with the various MOMs to query the state of system resources and with the Server for availability of jobs to execute. The interface to the Server is through the same API as used by the client commands. Note that the Scheduler interfaces with the Server with the same privilege as the PBS manager.

2.2 Defining PBS Terms

The following section defines important terms and concepts of PBS. The reader should review these definitions before beginning the planning process prior to installation of PBS. The terms are defined in an order that best allows the definitions to build on previous terms.

Node   A *node* to PBS is a computer system with a single *operating system* (OS) image, a unified virtual memory space, one or more CPUs and one or more IP addresses. Frequently, the term *execution host* is used for node. A computer such as the SGI Origin 3000, which contains multiple CPUs running under a single OS, is one node. Systems like the IBM SP and Linux clusters, which contain separate computational units each with their own OS, are collections of nodes. Nodes can be defined as either *cluster nodes* or *timeshared nodes*, as discussed below.

Cluster Node   A node whose purpose is geared toward running multi-node or parallel jobs is called a *cluster node*. If a cluster node has more than one virtual processor, the VPs may be assigned to different jobs (*job-shared*) or used to satisfy the requirements of a single job (*exclusive*). This ability to temporally allocate the entire node to the exclusive use of a single job is important for some multi-node parallel applications. Note that PBS enforces a one-to-one allocation scheme of cluster node VPs ensuring that the VPs are not over-allocated or over-subscribed between multiple jobs. (See also *node* and *virtual processors*.)

Timeshared Node   In contrast to cluster nodes are hosts that **always** service multiple jobs simultaneously, called *timeshared nodes*. Often the term *host* rather than node is used in conjunction with timeshared, as in *timeshared host*. A timeshared node will never be allocated exclusively or temporarily-shared. However, unlike cluster nodes, a timeshared node **can** be over-committed if the local policy specifies to do so. (See also *virtual processors*.)

Cluster   This is any collection of nodes controlled by a single instance of PBS (i.e., by one PBS Server).

Exclusive VP   An exclusive VP is one that is used by one and only one job at a time. A set of VPs is assigned exclusively to a job for the duration of that job. This is typically done to improve the performance of message-passing programs.

Temporarily- shared VP

A *temporarily-shared node* is one where one or more of its VPs are temporarily shared by jobs. If several jobs request multiple temporarily-shared nodes, some VPs may be allocated commonly to both jobs and some may be unique to one of the jobs. When a VP is allocated on a temporarily-shared basis, it remains so until all jobs using it are terminated. Then the VP may be re-allocated, either again for temporarily-shared use or for exclusive use.

If a host is defined as timeshared, it will never be allocated exclusively or temporarily-shared.

Load Balance

A policy wherein jobs are distributed across multiple timeshared hosts to even out the workload on each host. Being a policy, the distribution of jobs across execution hosts is solely a function of the Job Scheduler.

Queue

A *queue* is a named container for jobs within a Server. There are two types of queues defined by PBS, *routing* and *execution*. A *routing queue* is a queue used to move jobs to other queues including those that exist on different PBS Servers. Routing queues are similar to the NQS pipe queues. A job must reside in an *execution queue* to be eligible to run and remains in an execution queue during the time it is running. In spite of the name, jobs in a queue need not be processed in queue order (first-come first-served or *FIFO*).

Node Attribute

Nodes have attributes associated with them that provide control information. The attributes defined for nodes are: state, type (ntype), the list of jobs to which the node is allocated, properties, `max_running`, `max_user_run`, `max_group_run`, and both assigned and available resources ("`resources_assigned`" and "`resources_available`").

Node Property

A set of zero or more *properties* may be given to each node in order to have a means of grouping nodes for allocation. The property is nothing more than a string of alphanumeric characters (first character must be alphabetic) without meaning to PBS. The PBS administrator may assign to nodes whatever property names desired. Your PBS administrator will notify you of any locally defined properties.

Portable Batch System

PBS consists of one Job Server (`pbs_server`), one Job Scheduler (`pbs_sched`), and one or more execution servers (`pbs_mom`). The PBS System can be set up to distribute the workload to one large timeshared system, multiple time shared systems, a cluster of

nodes to be used exclusively or temporarily-shared, or any combination of these.

The remainder of this chapter provides additional terms, listed in alphabetical order.

Account   An *account* is arbitrary character string, which may have meaning to one or more hosts in the batch system. Frequently, account is used by sites for accounting or charge-back purposes.

Administrator   See Manager.

API   PBS provides an *Application Programming Interface (API)* which is used by the commands to communicate with the Server. This API is described in the **PBS Pro External Reference Specification**. A site may make use of the API to implement new commands if so desired.

Attribute   An *attribute* is an inherent characteristic of a parent object (Server, queue, job, or node). Typically, this is a data item whose value affects the operation or behavior of the object and can be set by the owner of the object. For example, the user can supply values for attributes of a job.

Batch or Batch Processing   This refers to the capability of running jobs outside of the interactive login environment.

Complex   A *complex* is a collection of hosts managed by one batch system. It may be made up of nodes that are allocated to only one job at a time or of nodes that have many jobs executing at once on each node or a combination of these two scenarios.

Destination   This is the location within PBS where a job is sent for processing. A destination may be a single queue at a single Server or it may map into multiple possible locations, tried in turn until one accepts the job.

Destination Identifier   This is a string that names the destination. It is composed two parts and has the format queue@server where server is the name of a PBS Server and queue is the string identifying a queue on that Server.

File Staging   *File staging* is the movement of files between a specified location and the execution host. See "Stage In" and "Stage Out" below.

Group ID (GID)   This unique number represents a specific group (see Group).

Group   *Group* refers to collection of system users (see Users). A user must be a member of a group and may be a member of more than one. Within UNIX and POSIX systems, membership in a group establishes one level of privilege. Group membership is also often used to control or limit access to system resources.

Hold   An artificial restriction which prevents a job from being selected for processing. There are three types of holds. One is applied by the job owner, another is applied by a PBS *Operator*, and a third applied by the system itself or the PBS *Manager*. (See also Operator and Manager in this glossary.)

Job or Batch Job   The basic execution object managed by the batch subsystem. A job is a collection of related processes which is managed as a whole. A job can often be thought of as a shell script running in a POSIX session. A non-singleton job consists of multiple tasks of which each is a POSIX session. One *task* will run the job shell script.

Manager   The *manager* is the person authorized to use all restricted capabilities of PBS. The Manager may act upon the Server, queues, or jobs. The Manager is also called the administrator.

Operator   A person authorized to use some but not all of the restricted capabilities of PBS is an *operator*.

Owner   The owner is the user who submitted the job to PBS.

POSIX   This acronym refers to the various standards developed by the "Technical Committee on Operating Systems and Application Environments of the IEEE Computer Society" under standard P1003.

Rerunable   If a PBS job can be terminated and its execution restarted from the beginning without harmful side effects, the job is rerunable.

Stage In   This process refers to moving a file or files to the execution host prior to the PBS job beginning execution.

Stage Out   This process refers to moving a file or files off of the execution host after the PBS job completes execution.

User   Each system *user* is identified by a unique character string (the user name) and by a unique number (the user id).

Task   *Task* is a POSIX session started by MOM on behalf of a job.

User ID (UID)   Privilege to access system resources and services is typically established by the *user id*, which is a numeric identifier uniquely assigned to each user (see User).

Virtual Processor (VP)   A node may be declared to consist of one or more *virtual processors (VPs)*. The term virtual is used because the number of VPs declared does not have to equal the number of real processors (CPUs) on the physical node. The default number of virtual processors on a node is the number of currently functioning physical processors; the PBS Manager can change the number of VPs as required by local policy. (See also *cluster node* and *timeshared node*.)

Chapter 3

Getting Started With PBS

This chapter introduces the user to the Portable Batch System, PBS. It describes new user-level features in this release, explains the different user interfaces, introduces the concept of a PBS "job", and shows how to set up your environment for running batch jobs with PBS.

3.1 New Features in PBS Pro 5.4

For users already familiar with PBS, the following is a list of new features and changes in PBS Pro release 5.4 which affect users. More detail is given in the indicated sections.

1. New "blocking qsub" option. (See "Requesting qsub Wait for Job Completion" on page 94.)

2. New option to control output file permissions. (See "Changing Job umask" on page 94.)

3. Features for using PBS within a DCE environment. (See "Running PBS in a DCE Environment" on page 114.)

Important: The full list of new features in this release of PBS is given in the **PBS Pro Administrator Guide**.

3.2 Introducing PBS Pro

From the user's perspective, a workload management system allows you to make more efficient use of your time. You specify the tasks you need executed. The system takes care of running these tasks and returning the results back to you. If the available computers are full, then the workload management system holds your work and runs it when the resources are available.

With PBS you create a *batch job* which you then submit to PBS. A batch job is simply a shell script containing the set of commands you want run on some set of execution machines. It also contains directives which specify the characteristics (attributes) of the job, and resource requirements (e.g. memory or CPU time) that your job needs. Once you create your PBS job, you can reuse it if you wish. Or, you can modify it for subsequent runs. For example, here is a simple PBS batch job:

```
#!/bin/sh
#PBS -l walltime=1:00:00
#PBS -l mem=400mb,ncpus=4
./subrun
```

Don't worry about the details just yet; the next chapter will explain how to create a batch job of your own.

PBS also provides a special kind of batch job called *interactive-batch*. An interactive-batch job is treated just like a regular batch job (in that it is queued up, and has to wait for resources to become available before it can run). Once it is started, however, the user's terminal input and output are connected to the job in what appears to be an `rlogin` session. It appears that the user is logged into one of the available execution machines, and the resources requested by the job are reserved for that job. Many users find this useful for debugging their applications or for computational steering.

3.3 The Two Faces of PBS

PBS provides two user interfaces: a command line interface (CLI) and a graphical user interface (GUI). The CLI lets you type commands at the system prompt. The GUI is a graphical point-and-click interface. Table 1 lists all the PBS Pro user and administrator commands. The "user commands" are discussed in this book; the "administrator commands" are discussed in the **PBS Pro Administrator Guide**. The subsequent chapters of this book will explain how to use both the CLI and GUI versions of the user commands to create, submit, and manipulate PBS jobs.

Table 1: PBS Pro User and Manager Commands

User Commands		Administrator Commands	
Command	**Purpose**	**Command**	**Purpose**
nqs2pbs	Convert from NQS	pbs-report	Report job statistics
pbs_rdel	Delete Adv. Reservation	pbs_hostid	Report host identifier
pbs_rstat	Status Adv. Reservation	pbs_hostn	Report host name(s)
pbs_rsub	Submit Adv.Reservation	pbs_probe	PBS diagnostic tool
pbsdsh	PBS distributed shell	pbs_rcp	File transfer tool
pbspoe	Job launcher: IBM POE	pbs_tclsh	TCL shell with PBS API
qalter	Alter job	pbsfs	Report fairshare usage
qdel	Delete job	pbsnodes	Node manipulation tool
qhold	Hold a job	printjob	Report job details
qmove	Move job	qdisable	Disable a queue
qmsg	Send message to job	qenable	Enable a queue
qorder	Reorder jobs	qmgr	PBS manager interface
qrls	Release hold on job	qrerun	Requeue a running job
qselect	Select jobs by criteria	qrun	Manually start a job
qsig	Send signal to job	qstart	Start a queue
qstat	Status job, queue, server	qstop	Stop a queue
qsub	Submit a job	qterm	Shutdown PBS Server
xpbs	Graphical User Interface	tracejob	Report job history
		xpbsmon	GUI monitoring tool
		xpbs -admin	Graphical User Interface

3.4 User's PBS Environment

In order to have your system environment interact seamlessly with PBS, there are several items that need to be checked. In many cases, your system administrator will have already set up your environment to work with PBS.

In order to use PBS to run your work, the following are needed:

> User must have access to the resources/hosts that the site has configured for PBS
> User must have a valid group/account on the execution hosts
> User must be able to transfer files between hosts (e.g. via `rcp` or `scp`)

3.5 Setting Up Your UNIX/Linux Environment

A user's job may not run if the user's start-up files (i.e `.cshrc`, `.login`, or `.profile`) contain commands which attempt to set terminal characteristics. Any such command sequence within these files should be skipped by testing for the environment variable **PBS_ENVIRONMENT**. This can be done as shown in the following sample `.login`:

```
...
setenv MANPATH /usr/man:/usr/local/man:$MANPATH
if ( ! $?PBS_ENVIRONMENT ) then
        do terminal settings here
endif
```

You should also be aware that commands in your startup files should not generate output when run under PBS. As in the previous example, commands that write to stdout should not be run for a PBS job. This can be done as shown in the following sample `.login`:

```
...
setenv MANPATH /usr/man:/usr/local/man:$MANPATH
if ( ! $?PBS_ENVIRONMENT ) then
        do terminal settings here
        run command with output here
endif
```

When a PBS job runs, the "exit status" of the last command executed in the job is reported by the job's shell to PBS as the "exit status" of the job. (We will see later that this is impor-

tant for job dependencies and job chaining.) However, the last command executed might not be the last command in your job. This can happen if your job's shell is `csh` on the execution host and you have a `.logout` there. In that case, the last command executed is from the `.logout` and not your job. To prevent this, you need to preserve the job's exit status in your `.logout` file, by saving it at the top, then doing an explict `exit` at the end, as shown below:

```
set EXITVAL = $status

previous contents of .logout here

exit $EXITVAL
```

Likewise, if the user's login shell is `csh` the following message may appear in the standard output of a job:

```
Warning: no access to tty, thus no job control in this shell
```

This message is produced by many `csh` versions when the shell determines that its input is not a terminal. Short of modifying `csh`, there is no way to eliminate the message. Fortunately, it is just an informative message and has no effect on the job.

3.6 Setting Up Your Windows Environment

This section discusses the setup needed for running PBS Pro under a Microsoft Windows environment.

3.6.1 Windows hosts.equiv File

Windows `hosts.equiv` file determines the list of non-Administrator accounts that are allowed access to the local host, that is, the host containing this file. This file also determines whether a remote user is allowed to submit jobs to the local PBS Server, with the user on the local host being a non-Administrator account.

This file is usually: `%WINDIR%\system32\drivers\etc\hosts.equiv`.

The format of the `hosts.equiv` file is as follows:

> `[+│-] ` *`hostname username`*

'+' means enable access whereas '-' means to disable access. If '+' or '-' is not specified, then this implies enabling of access. If only *`hostname`* is given, then users logged into that host are allowed access to like-named accounts on the local host. If only *`username`* is given, then that user has access to all accounts (except Administrator-type users) on the local host. Finally, if both *`hostname`* and *`username`* are given, then user at that host has access to like-named account on local host.

3.6.2 Windows rhosts File

The Windows rhosts file is located in the user's `HOMEDIR` with the format:

> *`hostname username`*

This file can also determine if a remote user is allowed to submit jobs to the local PBS Server, if the mapped user is an Administrator-type of account.

3.6.3 Windows User's HOMEDIR

Each Windows user is assumed to have a home directory (`HOMEDIR`) where his/her PBS job would initially be started. The home directory is also the starting location of files when users specify relative path arguments to `qsub/qalter -W stagein/stageout` options.

PBS determines a user's `HOMEDIR` in one of the following four ways:

1. The value of "Home directory" when one runs the command:

   `net user ` *`username`*

2. If (1) did not return a value, then it consults the user's `USER-PROFILE` environment variable and if `%USERPRO-FILE%\My Documents` exists, then uses the following path:

   `%USERPROFILE%\My Documents\PBS Output`

   For instance, for user `pbstest`, the `HOMEDIR` will be:

`c:\Documents and Settings\pbstest\My Documents\PBS Output`

3. If there is no `%USERPROFILE%\My Documents` directory, but `%USERPROFILE%` itself exists, then `HOMEDIR` is set to:

    `%USERPROFILE%\PBS Output`

4. If `%USERPROFILE%` does not exist, then the default `HOMEDIR` is finally:

    `%USERPROFILE%.PBS`

Under Windows 2000 (not XP), an Administrator can specify a home directory for a user via the Control-Panel->Settings->Users and Passwords dialog box, clicking on the Advanced tab, and then the Advanced button, which will give the directory structure for Users. Click on Users, select the username, and then right-mouse-click to bring up "Properties". Now click on the Properties tab and the home folder is available for update under the "Profile" tab. You will need to explicitly include the drive information for the home folder.

> **Important:** You must specify a directory for the home folder that is accessible to the user. If the directory has incorrect permissions, PBS will be unable to run jobs for the user.

3.7 Environment Variables

While we're on the topic of the user's environment, we should mention that there are a number of environment variables provided to the PBS job. Some are taken from the user's environment and carried with the job. Others are created by PBS. Still others can be explicitly created by the user for exclusive use by PBS jobs.

All PBS-provided environment variable names start with the characters "`PBS_`". Some are then followed by a capital O ("`PBS_O_`") indicating that the variable is from the job's originating environment (i.e. the user's). Appendix A gives a full listing of all environment variables provided to PBS jobs and their meaning.

The following short example lists some of the more useful variables, and typical values.

```
PBS_O_HOME=/u/james
PBS_O_LOGNAME=james
PBS_O_PATH=/usr/new/bin:/usr/local/bin:/bin
PBS_O_SHELL=/sbin/csh
PBS_O_TZ=PST8PDT
PBS_O_HOST=cray1.pbspro.com
PBS_O_WORKDIR=/u/james
PBS_O_QUEUE=submit
PBS_JOBNAME=INTERACTIVE
PBS_JOBID=16386.cray1.pbspro.com
PBS_QUEUE=crayq
PBS_ENVIRONMENT=PBS_INTERACTIVE
```

There are a number of ways that you can use these environment variables to make more efficient use of PBS. In the example above we see **PBS_ENVIRONMENT**, which we used earlier in this chapter to test if we were running under PBS. Another commonly used variable is **PBS_O_WORKDIR** which contains the name of the directory from which the user submitted the PBS job.

There are also two environment variables that you can set to affect the behavior of PBS. The environment variable **PBS_DEFAULT** defines the name of the default PBS Server. Typically, it corresponds to the system name of the host on which the Server is running. If **PBS_DEFAULT** is not set, the default is defined by an administrator established file (usually `/etc/pbs.conf`). The environment variable **PBS_DPREFIX** determines the prefix string which identifies directives in the job script. The default prefix string is "`#PBS`".

3.8 Temporary Scratch Space: TMPDIR

PBS creates an environment variable, TMPDIR, which contains the full path name to a temporary "scratch" directory created for each PBS job. The directory will be removed when the job terminates.

Chapter 4

Submitting a PBS Job

This chapter discusses the different parts of a PBS job and how to create and submit a PBS job. Topics such as requesting resources and specifying limits on jobs are also covered.

4.1 A Sample PBS Job

As we saw in the previous chapter, a PBS job is a shell script containing the resource requirements, job attributes, and the set of commands you wish to execute. Let's look at an example PBS job in detail:

```
1    #!/bin/sh
2    #PBS -l walltime=1:00:00
3    #PBS -l mem=400mb
4    #PBS -l ncpus=4
5    #PBS -j oe
6
7    ./subrun
```

The first line is standard for any shell script: it specifies which shell to use to execute the script. The Bourne shell (`sh`) is the default, but you can change this to your favorite shell.

Lines 2-5 are PBS directives. PBS reads down the shell script until it finds the first line that is not a valid PBS directive, then stops. It assumes the rest of the script is the list of commands or tasks that the user wishes to run. In this case, PBS sees lines 6-7 as being user commands.

We will see shortly how to use the `qsub` command to submit PBS jobs. Any option that you specify to the `qsub` command line can also be provided as a PBS directive inside the PBS script. PBS directives come in two types: resource requirements and job control options.

In our example above, lines 2-4 specify the "`-l`" resource list option, followed by a specific resource request. Specifically, lines 2-4 request 1 hour of wall-clock time, 400 megabytes (MB) of memory, and 4 CPUs.

Line 5 is not a resource directive. Instead it specifies how PBS should handle some aspect of this job. (Specifically, the "`-j oe`" requests that PBS *join* the `stdout` and `stderr` output streams of the job into a single stream.)

Finally line 7 is the command line for executing the program we wish to run: our example submarine simulation application, `subrun`. While only a single command is shown in this example (e.g. "`./subrun`"), you can specify as many programs, tasks, or job steps as you need.

4.2 Creating a PBS Job

There are several ways to create a PBS job. The most common are by using your favorite text editor, and by using the PBS graphical user interface (GUI). The rest of this chapter discusses creating and submitting jobs using the command line interface. The next chapter explains in detail how to use the `xpbs` GUI to create and submit your job.

4.3 Submitting a PBS Job

Let's assume the above example script is in a file called "mysubrun". We submit this script using the **qsub** command:

```
% qsub mysubrun
16387.cluster.pbspro.com
```

Notice that upon successful submission of a job, PBS returns a *job identifier* (e.g. "`16387.cluster.pbspro.com`" in the example above.) This identifier is a "handle" to the job. It's format will always be:

```
sequence-number.servername.domain
```

You'll need the job identifier for any actions involving the job, such as checking job status, modifying the job, tracking the job, or deleting the job.

In the previous example we submitted the job script to PBS, which in turn read the resource directive contained in the script. However, you can override resource attributes contained in the job script by specifying them on the command line. In fact, any job submission option or directive that you can specify inside the job script, you can also specify on the `qsub` command line. This is particularly useful if you just want to submit a single instance of your job, but you don't want to edit the script. For example:

```
% qsub -l ncpus=16 -l walltime=4:00:00 mysubrun
16388.cluster.pbspro.com
```

In this example, the 16 CPUs and 4 hours of wallclock time will override the values specified in the job script.

Note that you are *not* required to use a separate "`-l`" for each resource you request. You can combine multiple requests by separating them with a comma, thusly:

```
% qsub -l ncpus=16,walltime=4:00:00 mysubrun
16389.cluster.pbspro.com
```

The same rule applies to the job script as well, as the next example shows.

```
#!/bin/sh
#PBS -l walltime=1:00:00,mem=400mb
#PBS -l ncpus=4
#PBS -j oe

./subrun
```

4.4 How PBS Parses a Job Script

The `qsub` command scans the lines of the script file for directives. An initial line in the script that begins with the characters "`#!`" or the character "`:`" will be ignored and scanning will start with the next line. Scanning will continue until the first executable line, that is a line that is not blank, not a directive line, nor a line whose first non white space character is "`#`". If directives occur on subsequent lines, they will be ignored.

A line in the script file will be processed as a directive to `qsub` if and only if the string of characters starting with the first non white space character on the line and of the same length as the directive prefix matches the directive prefix (i.e. "`#PBS`"). The remainder of the directive line consists of the options to `qsub` in the same syntax as they appear on the command line. The option character is to be preceded with the "`-`" character.

If an option is present in both a directive and on the command line, that option and its argument, if any, will be ignored in the directive. The command line takes precedence. If an option is present in a directive and not on the command line, that option and its argument, if any, will be taken from there.

4.5 User Authorization

When the user submits a job from a system other than the one on which the PBS Server is running, system-level user authorization is required. This authorization is needed for submitting the job, for PBS to return output files (see also "Delivery of Output Files" on page 97), and for file staging (see also "Input/Output File Staging" on page 98).

> **Important:** The username under which the job is to be executed is selected according to the rules listed under the "`-u`" option to `qsub` (see "Specifying job userID" on page 39). The user submitting the job must be authorized to run the job under the execution user name (whether explicitly specified or not).

Such authorization is provided by any of the following three methods:

> **1.** The host on which `qsub` is run (i.e. the submission host) is trusted by the execution host. This permission may be granted at the system level by having the submission host as one of the entries in the execution host's `/etc/host.equiv` file naming the submission host. For file delivery and file staging, the host representing the source of the file must be in the receiving host's `/etc/host.equiv` file. Such entries require system administrator access.

> **2.** The host on which `qsub` is run (i.e. the submission host) is explicitly trusted by each execution host via the user's `.rhosts` file in his/her home directory. The `.rhosts` must contain an entry for the system on which the job executed, with the user name portion set to the name under which the job was executed.

For file delivery and file staging, the host representing the source of the file must be in the user's `.rhosts` file on the receiving host. It is recommended to have two lines per host, one with just the "base" host name and one with the full `host.domain.name`.

3. PBS may be configured to use the Secure Shell (ssh/scp) for system access and file transfers. If so configured, the user should set up his/her `.shosts` file or SSH keys in a similar manner as described in method 2 above. (For further discussion on using ssh/scp, see "Delivery of Output Files" on page 97.)

For example, the following entry in user `susan`'s `.rhosts` file on the execution host `server1` would permit user `susan` to run jobs submitted from her workstation wks031:

```
% cat .rhosts
wks031 susan
```

Furthermore, in order for Susan's output files from her job to be returned to her automatically by PBS, she would need to add an entry to her `.rhosts` file on her workstation naming the execution host `server1`.

```
% cat .rhosts
server1 susan
```

If instead, Susan has access to several execution hosts, she would need to add all of them to her `.rhosts` file:

```
% cat .rhosts
server1 susan
server2 susan
server3 susan
```

4.6 User Authorization: Windows Security Tokens

Under Windows, a job can be run in one of two ways. It can be run without requiring a user password (default), or the user can supply a password via `qsub` or `xpbs`. For a password-less job, PBS will create a security token authentication identifier for the user. This identifier will not be unique causing the job to not have access rights to some system resources like network shares. For a password-ed job, the authentication identifier will be

unique so users can access (within his/her job script) folders in a network share.

If you want to supply a password via `qsub`, use the `-Wpwd` option, and supply the password when prompted.

```
qsub -Wpwd="" job.script
```

The password specified will not be shown on screen and will be passed onto the program, which will then encrypt it and save it securely for use by the job.

The password can also be specified in `xpbs` using the "SUBMIT-PASSWORD:" entry box in the Submit window. The password you type in will not be shown on the screen.

Keep in mind that in a multi-node job, the password supplied will be propagated to all the sister nodes. This requires that the password be the same on user's accounts on all the nodes. The use of domain account for a multi-node job will be ideal in this case.

> **Important:** Because of enhanced security feature found in Windows 2003 Advanced Server, you may not be able to run non-passworded jobs.

4.7 Single-node vs Multi-node Jobs

In PBS jobs can be run either on a single system (single-node jobs) or on two or more systems (multi-node jobs). The basic usage of the two types of jobs is the same. The primary difference is in how you request resources for your job. Single-node jobs can simply state the number of CPUs and amount of individual resources needed. Multi-node jobs however, given their nature, have a more complex method of requesting resources, which enables you to specify how many different systems (nodes) your job needs, as well as the number of CPUs on each, and even how many tasks per CPU you wish to use, etc. The examples in this chapter apply to both types of jobs, however, the resource requests given are for single-node jobs. Additional details for multi-node jobs are given in Chapter 9 "Running Multi-node Jobs" on page 117.

4.8 PBS System Resources

You can request a variety of resources that can be allocated and used by your job, including CPUs, memory, time (walltime or cputime), and/or disk space. As we saw above, resources are specified using the "`-l resource_list`" option to `qsub` or in your job

script. Doing so defines the resources that are required by the job and establishes a limit to the amount of resource that can be consumed. If not set for a generally available resource, the limit is infinite.

The *resource_list* argument is of the form:

```
resource_name[=value][,resource_name[=value],...]
```

The resource values are specified using the following units:

node_spec   specifies the number and type of nodes, processors per node, tasks per node, etc, as needed by multi-node jobs. See "Running Multi-node Jobs" on page 117 for a complete explanation of use.

resc_spec   specifies a set of resources and the conditions under which they should be allocated to a single-node job. See section 4.10 "Single-Node Conditional Requests" on page 43.

time   specifies a maximum time period the resource can be used. Time is expressed in seconds as an integer, or in the form:

```
[[hours:]minutes:]seconds[.milliseconds]
```

size   specifies the maximum amount in terms of bytes (default) or words. It is expressed in the form `integer[suffix]`. The suffix is a multiplier defined in the following table. The size of a word is the word size on the execution host.

b or w	bytes or words.
kb or kw	Kilo (1024) bytes or words.
mb or mw	Mega (1,048,576) bytes or words.
gb or gw	Giga (1,073,741,824) bytes or words.

string   is comprised of a series of alpha-numeric characters containing no whitespace, beginning with an alphabetic character.

unitary   specifies the maximum amount of a resource which is expressed as a simple integer.

Different resources are available on different systems, often depending on the architecture of the computer itself. The table below lists the available resources that can be requested by PBS jobs on any system. Following that is a table of additional PBS resources that may be requested on computer systems running the Cray UNICOS operating system.

Table 2: PBS Resources Available on All Systems

Resource	Meaning and Usage	Units
arch	System architecture needed by job. `qsub -l arch=linux ...`	string
cput	Maximum, aggregate CPU time required by all processes in job. `qsub -l cput=5:00:00 ...`	time
file	Maximum disk space requirements for any single file to be created by job. `qsub -l file=300mb ...`	size
mem	Maximum amount of physical memory (RAM) required by job. `qsub -l mem=512mb ...`	size
ncpus	Number of CPUs (processors) required by job. `qsub -l ncpus=16 ...`	unitary
nice	Requested job priority (e.g. equivalent to "nice" on UNIX). `qsub -l nice=30 ...`	unitary
nodes	Number and/or type of nodes needed by job. (See also section 9.1 "Node Specification Syntax" on page 117.)	node_spec
pcput	Per-process maximum CPU time (i.e. for any single process in the job). `qsub -l pcput=3600 ...`	time
pmem	Per-process maximum amount of physical memory (i.e. for any single process of the job). `qsub -l pmem=100mb ...`	size

Table 2: PBS Resources Available on All Systems

Resource	Meaning and Usage	Units
`pvmem`	Per-process maximum amount of virtual memory (i.e. for any single process in the job). `qsub -l pvmem=200mb ...`	size
`resc`	Single-node variable resource specification string. (See also section 4.10 "Single-Node Conditional Requests" on page 43.)	resc_spec
`software`	Allows a user to specify software required by the job. The allowable values and effect on job placement is site dependent. Contact your PBS system administrator to learn what (if any) values for `software` have been configured at your site.	string
`vmem`	Maximum, aggregate amount of virtual memory used by all concurrent processes in the job. `qsub -l vmem=400mb ...`	size
`walltime`	Maximum amount of real time (wall-clock elapsed time) which the job needs to execute (run). `qsub -l walltime=4:00:00 ...`	time

On Cray systems running UNICOS 8 or later, there are additional resources that may be requested by PBS jobs, as shown below.

Table 3: PBS Resources on Cray UNICOS

Resource	Meaning	Units
`mppe`	The number of processing elements used by a single process in the job. `qsub -l mppe=512 ...`	unitary
`mppt`	Maximum amount of wall clock time used on the MPP in the job. `qsub -l mppt=4:00:00 ...`	time

Table 3: PBS Resources on Cray UNICOS

Resource	Meaning	Units
`mta, mtb...mth`	Maximum number of magnetic tape drives required in the corresponding device class of a or b. `qsub -l mta=1 ...`	unitary
`pf`	Maximum number of file system blocks that can be used by all process in the job. `qsub -l pf=1000 ...`	size
`pmppt`	Maximum amount of wall clock time used on the MPP by a single process in the job. `qsub -l pmppt=4:00:00 ...`	time
`pncpus`	Maximum number of processors used by any single process in the job. `qsub -l pncpus=4 ...`	unitary
`ppf`	Maximum number of file system blocks that can be used by a single process in the job. `qsub -l ppf=500 ...`	size
`procs`	Maximum number of processes in the job. `qsub -l procs=128 ...`	unitary
`psds`	Maximum number of data blocks on the SDS (secondary data storage) for any process in the job. `qsub -l psds=300 ...`	size
`sds`	Maximum number of data blocks on the SDS (secondary data storage) for the job. `qsub -l sds=1000 ...`	size

4.9 Job Submission Options

There are many options to the `qsub` command. The table below gives a quick summary of the available options; the rest of this chapter explains how to use each one.

Table 4: Options to the `qsub` Command

Option	Function and Page Reference
-A account_string	"Specifying a local account" on page 40
-a date_time	"Deferring execution" on page 38
-c interval	"Specifying job checkpoint interval" on page 39
-e path	"Redirecting output and error files" on page 35
-h	"Holding a job (delaying execution)" on page 38
-I	"Interactive-batch jobs" on page 42
-j *join*	"Merging output and error files" on page 41
-k *keep*	"Retaining output and error files on execution host" on page 41
-l resources_list -l resc=*resc_spec* -l nodes=*node_spec*	"PBS System Resources" on page 28 "Single-Node Conditional Requests" on page 43 "Running Multi-node Jobs" on page 117
-M user_list	"Setting e-mail recipient list" on page 36
-m MailOptions	"Specifying e-mail notification" on page 36
-N name	"Specifying a job name" on page 36
-o path	"Redirecting output and error files" on page 35
-p priority	"Setting a job's priority" on page 38
-q destination	"Specifying Queue and/or Server" on page 34
-r value	"Marking a job as "rerunnable" or not" on page 37
-S path_list	"Specifying which shell to use" on page 37
-u user_list	"Specifying job userID" on page 39
-V	"Exporting environment variables" on page 35
-v variable_list	"Expanding environment variables" on page 35

Table 4: Options to the `qsub` Command

Option	Function and Page Reference
`-W depend=list`	"Specifying Job Dependencies" on page 94
`-W group_list=list`	"Specifying job groupID" on page 40
`-W stagein=list`	"Input/Output File Staging" on page 98
`-W stageout=list`	"Input/Output File Staging" on page 98
`-W cred=dce`	"Running PBS in a DCE Environment" on page 114
`-W block=opt`	"Requesting qsub Wait for Job Completion" on page 94
`-W pwd='passwd'`	"Running PBS in a DCE Environment" on page 114
`-W umask=nnn`	"Changing Job umask" on page 94
`-z`	"Suppressing job identifier" on page 42

4.9.1 Specifying Queue and/or Server

The "`-q destination`" option to qsub allows you to specify a particular destination to which you want the job submitted. The *destination* names a queue, a Server, or a queue at a Server. The qsub command will submit the script to the Server defined by the *destination* argument. If the *destination* is a routing queue, the job may be routed by the Server to a new destination. If the `-q` option is not specified, the qsub command will submit the script to the default queue at the default Server. (See also the discussion of **PBS_DEFAULT** in "Environment Variables" on page 21.) The destination specification takes the following form:

```
-q [queue[@host]]
```

```
% qsub -q queue mysubrun

% qsub -q @server mysubrun
```

```
#!/bin/sh
#PBS -q queueName
...
```

```
% qsub -q queueName@serverName mysubrun

% qsub -q queueName@serverName.domain.com mysubrun
```

4.9.2 Redirecting output and error files

The "`-o path`" and "`-e path`" options to `qsub` allows you to specify the name of the files to which the standard output (stdout) and the standard error (stderr) file streams should be written. The path argument is of the form: `[hostname:]path_name` where *hostname* is the name of a host to which the file will be returned and *path_name* is the path name on that host. You may specify relative or absolute paths. If you specify only a file name, it is assumed to be relative to your home directory. The following examples illustrate these various options.

```
#!/bin/sh
#PBS -o /u/james/myOutputFile
#PBS -e /u/james/myErrorFile
```

```
% qsub -o myOutputFile mysubrun
% qsub -o /u/james/myOutputFile mysubrun
% qsub -o myWorkstation:/u/james/myOutputFile mysubrun
% qsub -e myErrorFile mysubrun
% qsub -e /u/james/myErrorFile mysubrun
% qsub -e myWorkstation:/u/james/myErrorFile mysubrun
```

4.9.3 Exporting environment variables

The "`-V`" option declares that all environment variables in the `qsub` command's environment are to be exported to the batch job.

```
% qsub -V mysubrun
```
```
#!/bin/sh
#PBS -V
...
```

4.9.4 Expanding environment variables

The "`-v variable_list`" option to `qsub` allows you to specify additional environment variables to be exported to the job. *variable_list* names environment variables from the qsub command environment which are made available to the job when it executes. The *variable_list* is a comma separated list of strings of the form `variable` or `variable=value`. These variables and their values are passed to the job.

```
$ qsub -v DISPLAY,myvariable=32 mysubrun
```

4.9.5 Specifying e-mail notification

The "-m MailOptions" defines the set of conditions under which the execution server will send a mail message about the job. The *MailOptions* argument is a string which consists of either the single character "n", or one or more of the characters "a", "b", and "e". If no email notification is specified, the default behavior will be the same as for "-m a".

> a   send mail when job is *aborted* by batch system
> b   send mail when job *begins* execution
> e   send mail when job *ends* execution
> n   *do not* send mail

```
% qsub -m ae mysubrun
```

```
#!/bin/sh
#PBS -m b
...
```

4.9.6 Setting e-mail recipient list

The "-M user_list" option declares the list of users to whom mail is sent by the execution server when it sends mail about the job. The *user_list* argument is of the form:

```
user[@host][,user[@host],...]
```

If unset, the list defaults to the submitting user at the qsub host, i.e. the job owner.

```
% qsub -M james@pbspro.com mysubrun
```

4.9.7 Specifying a job name

The "-N name" option declares a name for the job. The *name* specified may be up to and including 15 characters in length. It must consist of printable, non-whitespace characters

with the first character alphabetic, and contain no "special characters". If the `-N` option is not specified, the job name will be the base name of the job script file specified on the command line. If no script file name was specified and the script was read from the standard input, then the job name will be set to STDIN.

```
% qsub -N myName mysubrun
```

```
#!/bin/sh
#PBS -N myName
...
```

4.9.8 Marking a job as "rerunnable" or not

The "`-r y|n`" option declares whether the job is rerunable. To rerun a job is to terminate the job and requeue it in the execution queue in which the job currently resides. The *value* argument is a single character, either "y" or "n". If the argument is "y", the job is rerunable. If the argument is "n", the job is not rerunable. The default value is "y", rerunable.

```
% qsub -r n mysubrun
```

```
#!/bin/sh
#PBS -r n
...
```

4.9.9 Specifying which shell to use

The "`-S path_list`" option declares the shell that interprets the job script. The option argument *path_list* is in the form: `path[@host][,path[@host],...]` Only one path may be specified for any host named, and only one path may be specified without the corresponding host name. The path selected will be the one with the host name that matched the name of the execution host. If no matching host is found, then the path specified without a host will be selected, if present. If the `-S` option is not specified, the option argument is the null string, or no entry from the *path_list* is selected, then PBS will use the user's login shell on the execution host.

```
% qsub -S /bin/tcsh \
 mysubrun
```

```
#!/bin/sh
#PBS -S /bin/tcsh@mars,\
/usr/bin/tcsh@jupiter
...
```

4.9.10 Setting a job's priority

The "`-p priority`" option defines the priority of the job. The *priority* argument must be a integer between -1024 and +1023 inclusive. The default is no priority which is equivalent to a priority of zero. This option allows the user to specify a priority between jobs owned by that user. Note that it is only advisory— the Scheduler may choose to override your priorities in order to meet local scheduling policy. (If you need an absolute ordering of your jobs, see "Specifying Job Dependencies" on page 94.)

```
% qsub -p 120 mysubrun
```

```
#!/bin/sh
#PBS -p -300
...
```

4.9.11 Deferring execution

The "`-a date_time`" option declares the time after which the job is eligible for execution. The *date_time* argument is in the form: `[[[[CC]YY]MM]DD]hhmm[.SS]` where `CC` is the first two digits of the year (the century), `YY` is the second two digits of the year, `MM` is the two digits for the month, `DD` is the day of the month, `hh` is the hour, `mm` is the minute, and the optional `SS` is the seconds. If the month, `MM`, is not specified, it will default to the current month if the specified day `DD`, is in the future. Otherwise, the month will be set to next month. Likewise, if the day, `DD`, is not specified, it will default to today if the time `hhmm` is in the future. Otherwise, the day will be set to tomorrow. For example, if you submit a job at 11:15am with a time of "`1110`", the job will be eligible to run at 11:10am tomorrow. Other examples include:

```
% qsub -a 0700 mysubrun
```

```
#!/bin/sh
#PBS -a 10220700
...
```

4.9.12 Holding a job (delaying execution)

The "`-h`" option specifies that a *user hold* be applied to the job at submission time. The job will be submitted, then placed in a hold state. The job will remain ineligible to run until the hold is released. (For details on releasing a held job see "Holding and Releasing Jobs" on page 85.)

```
% qsub -h mysubrun
```

```
#!/bin/sh
#PBS -h
...
```

4.9.13 Specifying job checkpoint interval

The "-c interval" option defines the interval (in minutes) at which the job will be checkpointed, if this capability is provided by the operating system (i.e. under SGI IRIX and Cray Unicos). If the job executes upon a host which does not support checkpointing, this option will be ignored. The *interval* argument is specified as:

n   No checkpointing is to be performed.

s   Checkpointing is to be performed only when the Server executing the job is shutdown.

c   Checkpointing is to be performed at the default minimum time for the Server executing the job.

c=minutes   Checkpointing is to be performed at an interval of *minutes*, which is the integer number of minutes of CPU time used by the job. This value must be greater than zero.

u   Checkpointing is unspecified, thus resulting in the same behavior as "s".

If "-c" is not specified, the checkpoint attribute is set to the value "u".

```
% qsub -c c mysubrun
```

```
#!/bin/sh
#PBS -c c=10
...
```

4.9.14 Specifying job userID

The "-u user_list" option defines the user name under which the job is to run on the

execution system. If unset, the *user_list* defaults to the user who submitted the qsub command. The *user_list* argument is of the form: user[@host][,user[@host],...] Only one user name may be given per specified host, and only one of the user specifications may be supplied without the corresponding host specification. That user name will be used for execution on any host not named in the argument list. A named host refers to the host on which the job is queued for execution, not the actual execution host. Authorization must exist for the job owner to run as the specified user. (See "User Authorization" on page 26 for details.)

```
% qsub -u james@jupiter,barney@purpleplanet mysubrun
```

4.9.15 Specifying job groupID

The "-W group_list=g_list" option defines the group name under which the job is to run on the execution system. The *g_list* argument is of the form:

```
group[@host][,group[@host],...]
```

Only one group name may be given per specified host. Only one of the group specifications may be supplied without the corresponding host specification. That group name will used for execution on any host not named in the argument list. If not set, the *group_list* defaults to the primary group of the user under which the job will be run.

```
% qsub -W group_list=grpA,grpB@jupiter mysubrun
```

4.9.16 Specifying a local account

The "-A account_string" option defines the account string associated with the job. The *account_string* is an opaque string of characters and is not interpreted by the Server which executes the job. This value is often used by sites to track usage by locally defined account names.

Important: Under IRIX and Unicos, if the Account string is specified, it must be a valid account as defined in the system "User Data Base", UDB.

```
% qsub -A Math312 mysubrun
```

```
#!/bin/sh
#PBS -A accountNumber
...
```

4.9.17 Merging output and error files

The "`-j join`" option declares if the standard error stream of the job will be merged with the standard output stream of the job. A *join* argument value of `oe` directs that the two streams will be merged, intermixed, as standard output. A *join* argument value of `eo` directs that the two streams will be merged, intermixed, as standard error. If the *join* argument is `n` or the option is not specified, the two streams will be two separate files.

```
% qsub -j oe mysubrun
```

```
#!/bin/sh
#PBS -j eo
...
```

4.9.18 Retaining output and error files on execution host

The "`-k keep`" option defines which (if either) of standard output (STDOUT) or standard error (STDERR) of the job will be retained on the execution host. If set, this option overrides the path name for the corresponding file. If not set, neither file is retained on the execution host. The argument is either the single letter "e" or "o", or the letters "e" and "o" combined in either order. Or the argument is the letter "n". If "`-k`" is not specified, neither file is retained.

e   The standard error file is to be retained on the execution host. The file will be placed in the home directory of the user under whose user id the job executed. The file name will be the default file name given by: *job_name.**e**sequence* where `job_name` is the name specified for the job, and *sequence* is the sequence number component of the job identifier.

o   The standard output file is to be retained on the execution host. The file will be placed in the home directory of the user under whose user id the job executed. The file name will be the default file name given by: *job_name.**o**sequence* where `job_name` is the

name specified for the job, and *sequence* is the sequence number component of the job identifier.

eo   Both standard output and standard error will be retained.

oe   Both standard output and standard error will be retained.

n   Neither file is retained.

```
% qsub -k oe mysubrun
```

```
#!/bin/sh
#PBS -k eo
...
```

4.9.19 Suppressing job identifier

The "-z" option directs the qsub command to not write the job identifier assigned to the job to the command's standard output.

```
% qsub -z mysubrun
```

```
#!/bin/sh
#PBS -z
...
```

4.9.20 Interactive-batch jobs

The "-I" option declares that the job is to be run "interactively". The job will be queued and scheduled as any PBS batch job, but when executed, the standard input, output, and error streams of the job are connected through qsub to the terminal session in which qsub is running. If the -I option is specified on the command line or in a script directive, the job is an interactive job. If a script is given, it will be processed for directives, but any executable commands will be discarded. When the job begins execution, all input to the job is from the terminal session in which qsub is running. When an interactive job is submitted, the qsub command will not terminate when the job is submitted. qsub will remain running until the job terminates, is aborted, or the user interrupts qsub with a SIGINT (the control-C key). If qsub is interrupted prior to job start, it will query if the user wishes to exit. If the user responds "yes", qsub exits and the job is aborted.

Once the interactive job has started execution, input to and output from the job pass through qsub. Keyboard-generated interrupts are passed to the job. Lines entered that

begin with the tilde ('~') character and contain special sequences are interpreted by `qsub` itself. The recognized special sequences are:

> ~.   `qsub` terminates execution. The batch job is also terminated.
>
> ~susp   Suspend the `qsub` program if running under the C shell. "susp" is the suspend character, usually CNTL-Z.
>
> ~asusp   Suspend the input half of `qsub` (terminal to job), but allow output to continue to be displayed. Only works under the C shell. "asusp" is the auxiliary suspend character, usually CNTL-Y.

4.10 Single-Node Conditional Requests

PBS Pro offers the ability to use boolean logic in the specification of certain resources (such as architecture, memory, wallclock time, and CPU count) *within a single node*. A new resource specification string (resc_spec) attribute has been added called "`resc`"). Used with the resource list option ("`-l`") to the `qsub` command, this feature provides more control over selecting nodes on which to run your job.

> **Important:**   At this time, this feature controls the selection of single nodes, with the meaning of "allocate my job a node with the following properties". This feature does not apply to multi-node jobs.

For example, say you wanted to submit a job that can run on either the Solaris or Irix operating system, and you want PBS to run the job on the first available node of either type. You could add the following "`resc`" specification to your `qsub` command line (or your job).

```
% qsub -l resc="(arch=='solaris7') || (arch=='irix')" mysubrun
```

```
#!/bin/sh
#PBS -l resc="(arch=='solaris7')||(arch=='irix')"
#PBS -l mem=100MB
#PBS -l ncpus=4
...
```

You could in fact combine all three of the lines in the above example into a single `resc_spec` specification, if you so desired:

qsub -l resc="((arch=='solaris7') || (arch=='irix')) && (mem=100MB) &&(ncpus=4)"

The following example shows requesting different memory amounts depending on the architecture that the job runs on:

qsub -l resc="((arch=='solaris7') && (mem=100MB)||((arch=='irix')&&(mem=1GB))"

Furthermore, it is possible to specify multiple resource specification strings. The first `resc` specification will be evaluated. If it can be satisfied, then it will be used. If not, then next `resc` string will be used. For example:

```
qsub \
-l resc="(ncpus=16)&& (mem=1GB)  &&(walltime=1:00)" \
-l resc="(ncpus=8) && (mem=512MB)&&(walltime=2:00)" \
-l resc="(ncpus=4) && (mem=256MB)&&(walltime=4:00)" ...
```

indicates that you want 16 CPUs, but if you can't have 16 CPUs, then give you 8 with half the memory and twice the wall-clock time. But if you can't have 8 CPUs, then give you four and 1/4 the memory, and four times the walltime.

This is different then putting them all into one `resc` specification. If you were to do

qsub -l resc= "(ncpus=16)||(ncpus=8)||(ncpus=4)" ...

you would be requesting the first available node which has either 16, 8, or 4 CPUs. In this case, PBS doesn't go through all the nodes checking for 16 first, then 8, then 4, as it does when using multiple `resc` specifications.

> **Important:** Note the difference between "==" (comparison) and "=" (assignment) within a `resc_spec`. The comparison operators only impact which node is selected for the job, they do not establish limits on the job. The assignment operator, however, is equivalent to separate specifications of `-l  mem=x` and `-l walltime=y` in order to set the job limits.

You can do more than just using the equality and assignment operators. You can describe the characteristics of a node, but not request them. For example, if you were to request the following:

```
qsub \
-l resc="(ncpus>16)&&(mem>=2GB)" -lncpus=2 -lmem=100MB
```

you would be indicating that you want a node with more then 16 CPUs but you only want two of them allocated to your job:

4.11 Job Attributes

A PBS job has the following attributes, which may be set by the various options to `qsub` (for details see section 4.9 "Job Submission Options" on page 32).

Account_Name   Reserved for local site accounting. If specified (using the -A option to `qsub`) this value is carried within the job for its duration, and is included in the job accounting records.

Checkpoint   If supported by the Server implementation and the host operating system, the checkpoint attribute determines when checkpointing will be performed by PBS on behalf of the job. The legal values for checkpoint are described under the `qalter` and `qsub` commands.

depend   The type of inter-job dependencies specified by the job owner.

Error_Path   The final path name for the file containing the job's standard error stream. See the `qsub` and `qalter` command description for more detail.

Execution_Ti me   The time after which the job may execute. The time is maintained in seconds since Epoch. If this time has not yet been reached, the job will not be scheduled for execution and the job is said to be in *wait* state.

group_list   A list of *group_names@hosts* which determines the group under which the job is run on a given host. When a job is to be placed into execution, the Server will select a group name according to the rules specified for use of the `qsub` command.

Hold_Types   The set of holds currently applied to the job. If the set is not null, the job will not be scheduled for execution and is said to be in the *hold*

state. Note, the *hold* state takes precedence over the `wait` state.

Job_Name
: The name assigned to the job by the `qsub` or `qalter` command.

Join_Path
: If the `Join_Paths` attribute is `oe`, then the job's standard error stream will be merged, inter-mixed, with the job's standard output stream and placed in the file determined by the `Output_Path` attribute. The `Error_Path` attribute is maintained, but ignored. However, if the `Join_Paths` attribute is `eo`, then the job's standard output stream will be merged, inter-mixed, with the job's standard error stream and placed in the file determined by the `Error_Path` attribute, and the `Output_Path` attribute will be ignored.

Keep_Files
: If `Keep_Files` contains the values `"o"` `KEEP_OUTPUT` and/or `"e"` `KEEP_ERROR` the corresponding streams of the batch job will be retained on the execution host upon job termination. `Keep_Files` overrides the `Output_Path` and `Error_Path` attributes.

Mail_Points
: Identifies when the Server will send email about the job.

Mail_Users
: The set of users to whom mail may be sent when the job makes certain state changes.

Output_Path
: The final path name for the file containing the job's standard output stream. See the `qsub` and `qalter` command description for more detail.

Priority
: The job scheduling priority assigned by the user.

Rerunable
: The rerunable flag given by the user.

Resource_List
: The resource list is a set of *name=value* strings of the resources required by the job. The value also establishes the limit of usage of that resource. If not set, the value for a resource may be determinate by a queue or Server default established by the administrator.

Shell_Path_List
: A set of absolute paths of the program to process the job's script file.

stagein   The list of files to be staged in prior to job execution.

stageout   The list of files to be staged out after job execution.

User_List   The list of *user@hosts* which determines the username under which the job is run on a given host.

Variable_Lis   This is the list of environment variables passed with the *Queue Job*
t   batch request.

comment   An attribute for displaying comments about the job from the system. Visible to any client.

The following attributes are read-only, they are established by the Server and are visible to the user but cannot be set or changed by a user.

alt_id

For a few systems, such as Irix 6.x running Array Services, the session id is insufficient to track which processes belong to the job. Where a different identifier is required, it is recorded in this attribute. If set, it will also be recorded in the end-of-job accounting record. For Irix 6.x running Array Services, the alt_id attribute is set to the Array Session Handle (ASH) assigned to the job.

ctime   The time that the job was created.

etime   The time that the job became eligible to run, i.e. in a queued state while residing in an execution queue.

exec_host   If the job is running, this is set to the name of the host or hosts on which the job is executing. The format of the string is "node/ N[*C][+...]", where "node" is the name of a node, "N" is process or task slot on that node, and "C" is the number of CPUs allocated to the job. C does not appear if it is one.

egroup   If the job is queued in an execution queue, this attribute is set to the group name under which the job is to be run. [This attribute is available only to the batch administrator.]

`euser`	If the job is queued in an execution queue, this attribute is set to the user name under which the job is to be run. [This attribute is available only to the batch administrator.]
`hashname`	The name used as a basename for various files, such as the job file, script file, and the standard output and error of the job. [This attribute is available only to the batch administrator.]
`interactive`	True if the job is an interactive PBS job.
`Job_Owner`	The login name on the submitting host of the user who submitted the batch job.
`job_state`	The state of the job.
`mtime`	The time that the job was last modified, changed state, or changed locations.
`qtime`	The time that the job entered the current queue.
`queue`	The name of the queue in which the job currently resides.
`queue_rank`	An ordered, non-sequential number indicating the job's position within the queue. This is provided as an aid to the Scheduler. [This attribute is available to the batch manager only.]
`queue_type`	An identification of the type of queue in which the job is currently residing. This is provided as an aid to the Scheduler. [This attribute is available to the batch manager only.]
`resources_used`	The amount of resources used by the job. This is provided as part of job status information if the job is running.
`server`	The name of the Server which is currently managing the job.
`session_id`	If the job is running, this is set to the session id of the first executing task.
`substate`	A numerical indicator of the substate of the job. The substate is used by the PBS Server internally. The attribute is visible to privileged clients, such as the Scheduler.

Chapter 5

Using the xpbs GUI

The PBS graphical user interface is called **xpbs**, and provides a user-friendly, point and click interface to the PBS commands. xpbs utilizes the tcl/tk graphics toolsuite, while providing the user with the same functionality as the PBS CLI commands. In this chapter we introduce xpbs, and show how to create a PBS job using xpbs.

5.1 User's **xpbs** Environment

Depending on how PBS is installed at your site, you may need to allow xpbs to display on your workstation. However, if the PBS client commands are installed locally on your workstation, you can skip this section. (Ask your PBS administrator if you are unsure.)

Make sure your X-Windows session is set to permit the xpbs client to connect to your local X-server. Do this by running the xhost command with the name of the host from which you will be running xpbs, as shown in the example below:

```
% xhost + server.pbspro.com
```

Next, on the system from which you will be running xpbs, set your X-Windows **DIS-PLAY** variable to your local workstation. For example, if using the C-shell:

```
% setenv DISPLAY myWorkstation:0.0
```

However, if you are using the Bourne or Korn shell, type the following:

```
% export DISPLAY=myWorkstation:0.0
```

5.1.1 Starting xpbs

Once your PBS environment is setup, launch xpbs:

```
% xpbs &
```

Doing so will bring up the main xpbs window, as shown below.

5.2 Introducing the xpbs Main Display

The main window or display of xpbs is comprised of five collapsible subwindows or *panels*. Each panel contains specific information. Top to bottom, these panel are: the Menu Bar, Hosts panel, Queues panel, Jobs panel, and the Info panel

5.2.1 xpbs Menu Bar

The Menu Bar is composed of a row of command buttons that signal some action with a click of the left mouse button. The buttons are:

Manual Update	forces an update of the information on hosts, queues, and jobs.
Auto Update	sets an automatic update of information every user-specified number of minutes.
Track Job	for periodically checking for returned output files of jobs.
Preferences	for setting parameters such as the list of server host(s) to query.
Help	contains some help information.
About	givens general information about the xpbs developer.
Close	for exiting xpbs plus saving the current setup information.
	.
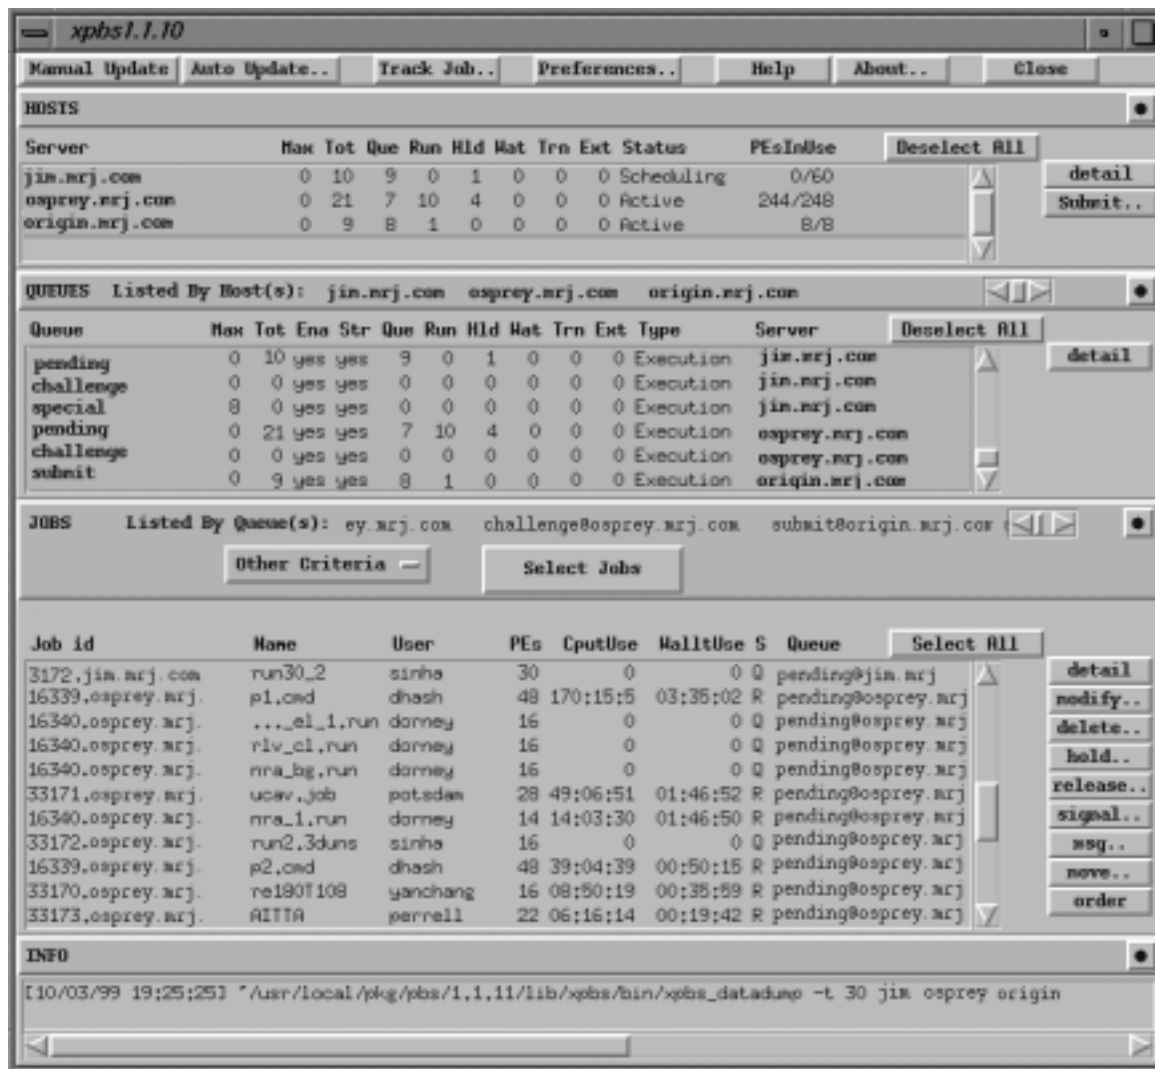

5.2.2 xpbs Hosts Panel

The Hosts panel is composed of a leading horizontal HOSTS bar, a listbox, and a set of command buttons. The HOSTS bar contains a minimize/maximize button, identified by a dot or a rectangular image, for displaying or iconizing the Hosts region. The listbox displays information about favorite Server host(s), and each entry is meant to be selected via a single <left mouse button> click, <shift key> plus <left mouse button> click for contiguous selection, or <cntrl key> plus <left mouse button> click for non-contiguous selection.

To the right of the Hosts Panel are a series of buttons that represent actions that can be per-

formed on selected hosts(s). (Use of these buttons will be explained in detail below.) The buttons are:

> detail   provides information about selected Server host(s). This func-
> tionality can also be achieved by double clicking on an entry in
> the Hosts listbox.
>
> submit   for submitting a job to any of the queues managed by the
> selected host(s).
>
> terminate   for terminating PBS Servers on selected host(s). (-admin only)

Note that some buttons are only visible if `xpbs` is started with the "`-admin`" option, which requires manager or operator privilege to function.

The middle portion of the Hosts Panel has abbreviated column names indicating the information being displayed, as the following table shows:

Table 5: xpbs Server Column Headings

Heading	Meaning
Max	Maximum number of jobs permitted
Tot	Count of jobs currently enqueued in any state
Que	Count of jobs in the Queued state
Run	Count of jobs in the Running state
Hld	Count of jobs in the Held state
Wat	Count of jobs in the Waiting state
Trn	Count of jobs in the Transiting state
Ext	Count of jobs in the Exiting state
Status	Status of the corresponding Server
PEsInUse	Count of Processing Elements (CPUs, PEs, Nodes) in Use

5.2.3 xpbs Queues Panel

The Queues panel is composed of a leading horizontal QUEUES bar, a listbox, and a set of command buttons. The QUEUES bar lists the hosts that are consulted when listing queues; the bar also contains a minimize/maximize button for displaying or iconizing the Queues panel. The listbox displays information about queues managed by the Server host(s)

selected from the Hosts panel; each listbox entry is meant to be selected (highlighted) via a single <left mouse button> click, <shift key> plus <left mouse button> click for contiguous selection, or <cntrl key> plus <lift mouse button> click for non-contiguous selection.

To the right of the Queues Panel area are a series of buttons that represent actions that can be performed on selected queue(s).

detail	provides information about selected queue(s). This functionality can also be achieved by double clicking on a Queue listbox entry.
stop	for stopping the selected queue(s). (-admin only)
start	for starting the selected queue(s). (-admin only)
disable	for disabling the selected queue(s). (-admin only)
enable	for enabling the selected queue(s). (-admin only)

The middle portion of the Queues Panel has abbreviated column names indicating the information being displayed, as the following table shows:

Table 6: xpbs Queue Column Headings

Heading	Meaning
Max	Maximum number of jobs permitted
Tot	Count of jobs currently enqueued in any state
Ena	Is queue enabled? yes or no
Str	Is queue started? yes or no
Que	Count of jobs in the Queued state
Run	Count of jobs in the Running state
Hld	Count of jobs in the Held state
Wat	Count of jobs in the Waiting state
Trn	Count of jobs in the Transiting state
Ext	Count of jobs in the Exiting state
Type	Type of queue: execution or route
Server	Name of Server on which queue exists

5.2.4 xpbs Jobs Panel

The Jobs panel is composed of a leading horizontal JOBS bar, a listbox, and a set of command buttons. The JOBS bar lists the queues that are consulted when listing jobs; the bar also contains a minimize/maximize button for displaying or iconizing the Jobs region. The listbox displays information about jobs that are found in the queue(s) selected from the Queues listbox; each listbox entry is meant to be selected (highlighted) via a single <left mouse button> click, <shift key> plus <left mouse button> click for contiguous selection, or <cntrl key> plus <left mouse button> click for non-contiguous selection.

The region just above the Jobs listbox shows a collection of command buttons whose labels describe criteria used for filtering the Jobs listbox contents. The list of jobs can be selected according to the owner of jobs (Owners), job state (Job_States), name of the job (Job_Name), type of hold placed on the job (Hold_Types), the account name associated with the job (Account_Name), checkpoint attribute (Checkpoint), time the job is eligible for queueing/execution (Queue_Time), resources requested by the job (Resources), priority attached to the job (Priority), and whether or not the job is rerunnable (Rerunnable).

The selection criteria can be modified by clicking on any of the appropriate command buttons to bring up a selection box. The criteria command buttons are accompanied by a *Select Jobs* button, which when clicked, will update the contents of the Jobs listbox based on the new selection criteria. Note that only jobs that meet ***all*** the selected criteria will be displayed.

Finally, to the right of the Jobs panel are the following command buttons, for operating on selected job(s):

detail	provides information about selected job(s). This functionality can also be achieved by double-clicking on a Jobs listbox entry.
modify	for modifying attributes of the selected job(s).
delete	for deleting the selected job(s).
hold	for placing some type of hold on selected job(s).
release	for releasing held job(s).
signal	for sending signals to selected job(s) that are running.
msg	for writing a message into the output streams of selected job(s).
move	for moving selected job(s) into some specified destination.
order	for exchanging order of two selected jobs in a queue.
run	for running selected job(s). (-admin only)
rerun	for requeueing selected job(s) that are running. (-admin only)

The middle portion of the Jobs Panel has abbreviated column names indicating the information being displayed, as the following table shows:

Table 7: xpbs Job Column Headings

Heading	Meaning
Job id	Job Identifier
Name	Name assigned to job, or script name
User	User name under which job is running
PEs	Number of Processing Elements (CPUs) requested
CputUse	Amount of CPU time used
WalltUse	Amount of wall-clock time used
S	State of job
Queue	Queue in which job resides

5.2.5 xpbs Info Panel

The Info panel shows the progress of the commands' executed by `xpbs`. Any errors are written to this area. The INFO panel also contains a minimize/maximize button for displaying or iconizing the Info panel.

5.2.6 xpbs Keyboard Tips

There are a number of shortcuts and key sequences that can be used to speed up using `xpbs`. These include:

Tip 1. All buttons which appear to be depressed into the dialog box/sub-window can be activated by pressing the return/enter key.

Tip 2. Pressing the tab key will move the blinking cursor from one text field to another.

Tip 3. To contiguously select more than one entry: click <left mouse button> then drag the mouse across multiple entries.

Tip 4. To non-contiguously select more than one entry: hold the <cntrl key> while clicking the <left mouse button> on the desired entries.

5.3 Setting xpbs Preferences

In the Menu Bar at the top of the main xpbs window is the Preferences button. Clicking it will bring up a dialog box that allows you to customize the behavior of xpbs:

1. Define Server hosts to query
2. Select wait timeout in seconds
3. Specify which xterm command to use
4. Specify which rsh/ssh command to use
5.4 Relationship Between PBS and `xpbs`

`xpbs` is built on top of the PBS client commands, such that all the features of the command line interface are available thru the GUI. Each "task" that you perform using `xpbs` is converted into the necessary PBS command and then run on your behalf.

Table 8: xpbs Buttons and PBS Commands

| Location	Command Button	PBS Command
Hosts Panel	detail	qstat -B -f *selected server_host(s)*
Hosts Panel	submit	qsub *options selected server(s)*
Hosts Panel	terminate *	qterm *selected server_host(s)*
Queues Panel	detail	qstat -Q -f *selected queue(s)*
Queues Panel	stop *	qstop *selected queue(s)*
Queues Panel	start *	qstart *selected queue(s)*
Queues Panel	enable *	qenable *selected queue(s)*
Queues Panel	disable *	qdisable *selected queue(s)*
Jobs Panel	detail	qstat -f *selected job(s)*
Jobs Panel	modify	qalter *selected job(s)*
Jobs Panel	delete	qdel *selected job(s)*
Jobs Panel	hold	qhold *selected job(s)*
Jobs Panel	release	qrls *selected job(s)*
Jobs Panel	run	qrun *selected job(s)*
Jobs Panel	rerun	qrerun *selected job(s)*
Jobs Panel	signal	qsig *selected job(s)*
Jobs Panel	msg	qmsg *selected job(s)*
Jobs Panel	move	qmove *selected job(s)*
Jobs Panel	order	qorder *selected job(s)*

* Indicates command button is visible only if xpbs is started with the "-admin" option.

5.5 How to Submit a Job Using `xpbs`

To submit a job using `xpbs`, perform the following steps:

First, select a host from the HOSTS listbox in the main `xpbs` display to which you wish to submit the job.

Next, click on the *Submit* button located next to the HOSTS panel. The *Submit* button brings up the Submit Job Dialog box (see below) which is composed of four distinct regions. The Job Script File region is at the upper left. The OPTIONS region containing various widgets for setting job attributes is scattered all over the dialog box. The OTHER OPTIONS is located just below the Job Script file region, and COMMAND BUTTONS region is at the bottom.
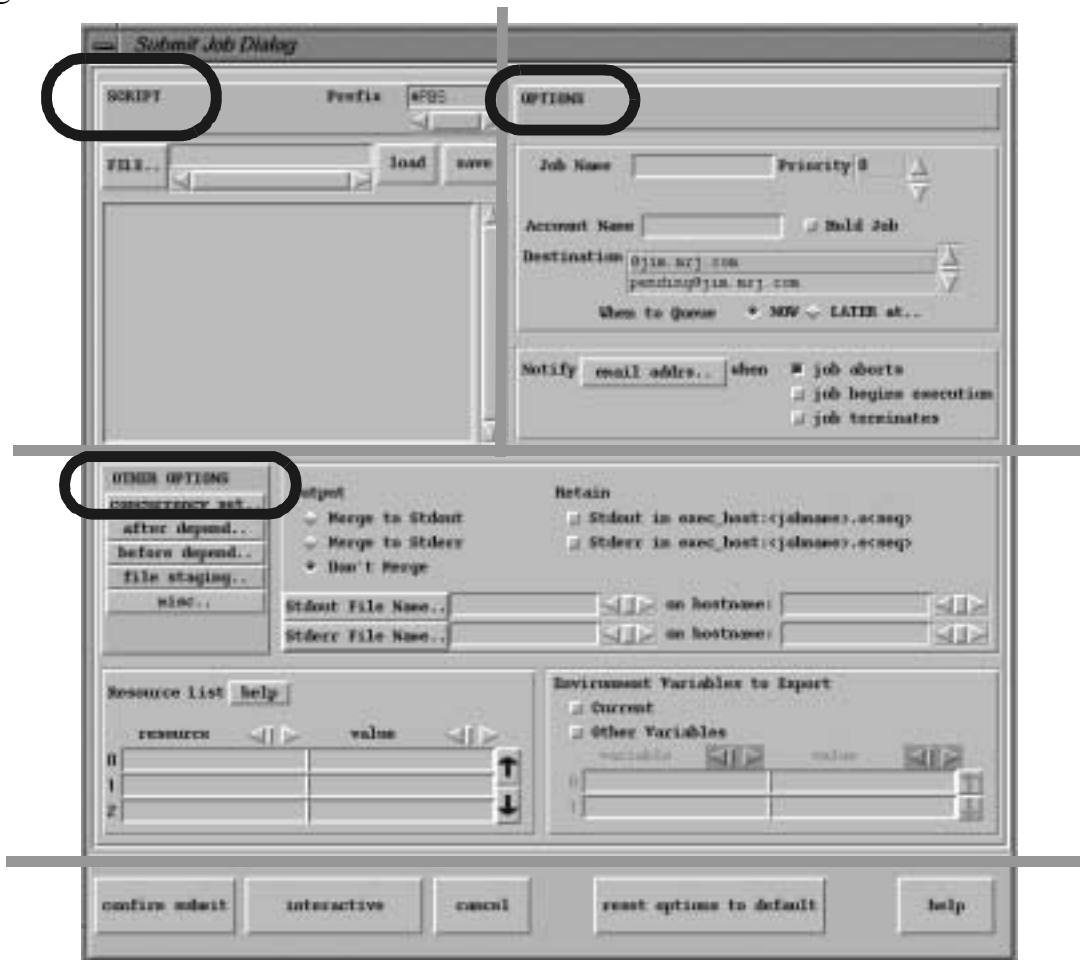

The job script region is composed of a header box, the text box, FILE entry box, and two buttons labeled *load* and *save.* If you have a script file containing PBS options and execut-

able lines, then type the name of the file on the FILE entry box, and then click on the *load* button. Alternatively, you may click on the *FILE* button, which will display a File Selection browse window, from which you may point and click to select the file you wish to open. The File Selection Dialog window is shown below. Clicking on the *Select File* button will load the file into xpbs, just as does the *load* button described above.
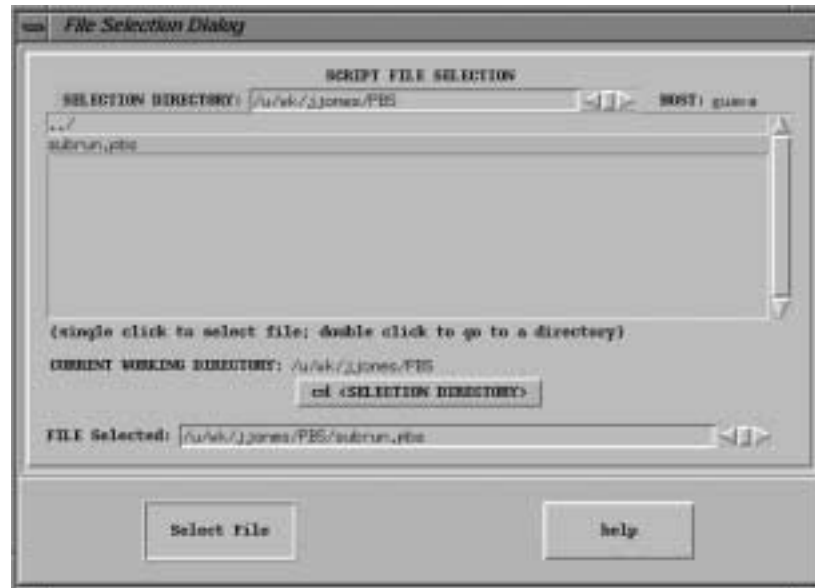

The various fields in the Submit window will get loaded with values found in the script file. The script file text box will only be loaded with executable lines (non-PBS) found in the script. The job script header box has a *Prefix* entry box that can be modified to specify the PBS directive to look for when parsing a script file for PBS options.

If you don't have a existing script file to load into xpbs, you can start typing the executable lines of the job in the file text box.

Next, review the Destination listbox. This box lists all the queues found in the host that you selected. A special entry called "@host" refers to the default queue at the indicated host. Select appropriately the destination queue for the job.

Next, define any required resources in the Resource List subwindow. Finally, review the optional settings to see if any should apply to this job.

For example:

    o   Use the one of the buttons in the "Output" region to merge output and error files.

    o   Use "Stdout File Name" to define standard output file and to redirect output

    o   Use the "Environment Variables to Export" subwindow to have current environment variables exported to the job.

    o   Use the "Job Name" field in the OPTIONS subwindow to give the job a name.

    o   Use the "Notify email address" and one of the buttons in the OPTIONS subwindow to have PBS send you mail when the job terminates.

Now that the script is built you have four options of what to do next:

    Reset options to default
    Save the script to a file
    Submit the job as a batch job
    Submit the job as an interactive-batch job

Reset clears all the information from the submit job dialog box, allowing you to create a job from a fresh start.

Use the FILE. field (in the upper left corner) to define a filename for the script. Then press the *Save* button. This will cause a PBS script file to be generated and written to the named file.

Pressing the *Confirm Submit* button at the bottom of the Submit window will submit the PBS job to the selected destination. xpbs will display a small window containing the job identifier returned for this job. Clicking *OK* on this window will cause it and the Submit window to be removed from your screen.

Alternatively, you can submit the job as an interactive-batch job, by clicking the *Interactive* button at the bottom of the Submit Job window. Doing so will cause a xterminal window (xterm) to be launched, and within that window a PBS interactive-batch job submitted. (For details and restrictions on use, see "Interactive-batch jobs" on page 42.)

5.6 Exiting xpbs

Click on the *Close* button located in the Menu bar to leave `xpbs`. If any settings have been changed, `xpbs` will bring up a dialog box asking for a confirmation in regards to saving state information. The settings will be saved in the `xpbs` configuration file, and will be used the next time you run `xpbs`.

5.7 The xpbs Configuration File

Upon exit, the `xpbs` state may be written to the user's `$HOME/.xpbsrc` file. Information saved includes: the selected host(s), queue(s), and job(s); the different jobs listing criteria; the view states (i.e. minimized/maximized) of the Hosts, Queues, Jobs, and INFO regions; and all settings in the Preferences section. In addition, there is a system-wide `xpbs` configuration file, maintained by the PBS Administrator, which is used in the absence of a user's personal `.xpbsrc` file.

5.8 Widgets Used in xpbs

The various panels, boxes, and regions (collectively called "widgets") of `xpbs` and how they are manipulated are described in the following sections. A *listbox* can be multi-selectable (a number of entries can be selected/highlighted using a mouse click) or single-selectable (one entry can be highlighted at a time).

For a multi-selectable listbox, the following operations are allowed:

    a. single click with mouse button 1 to select/highlight an entry.

    b. shift key + mouse button 1 to contiguously select more than one entry.

    c. cntrl key + mouse button 1 to non-contiguously select more than one entry. NOTE: For systems running Tk versions prior to 4.0, the newly selected item is reshuffled to appear next to already selected items.

    d. click the *Select All/Deselect All* button to select all entries or deselect all entries at once.

    e. double clicking an entry usually activates some action that uses the selected entry as a parameter.

A *scrollbar* usually appears either vertically or horizontally and contains 5 distinct areas that are mouse clicked to achieve different effects:

top arrow	Causes the view in the associated widget to shift up by one unit (i.e. the object appears to move down one unit in its window). If the button is held down the action will auto-repeat.
slider	Pressing button 1 in this area has no immediate effect except to cause the slider to appear sunken rather than raised. However, if the mouse is moved with the button down then the slider will be dragged, adjusting the view as the mouse is moved.
bottom arrow	Causes the view in the associated window to shift down by one unit (i.e. the object appears to move up one unit in its window). If the button is held down the action will auto-repeat.
top gap	(The area between the top arrow and the slider). Causes the view in the associated window to shift up by one less than the number of units in the window (i.e. the portion of the object that used to appear at the very top of the window will now appear at the very bottom). If the button is held down the action will auto-repeat.
bottom gap	(The area between the bottom arrow and the slider.) Causes the view in the associated window to shift down by one less than the number of units in the window (i.e. the portion of the object that used to appear at the very bottom of the window will now appear at the very top). If the button is held down the action will auto-repeat.

An *entry* widget brought into focus with a click of the left mouse button. To manipulate this widget, simply type in the text value. Use of arrow keys, mouse selection of text for deletion or overwrite, copying and pasting with sole use of mouse buttons are permitted. This widget is usually accompanied by a scrollbar for horizontally scanning a long text entry string.

A *matrix of entry boxes* is usually shown as several rows of entry widgets where a number of entries (called fields) can be found per row. The matrix is accompanied by up/down arrow buttons for paging through the rows of data, and each group of fields gets one scrollbar for horizontally scanning long entry strings. Moving from field to field can be done using the <Tab> (move forward), <Cntrl-f> (move forward), or <Cntrl-b> (move backward) keys.

A *spinbox* is a combination of an entry widget and a horizontal scrollbar. The entry widget will only accept values that fall within a defined list of valid values, and incrementing through the valid values is done by clicking on the up/down arrows.

A *button* is a rectangular region appearing either raised or pressed that invokes an action when clicked with the left mouse button. When the button appears pressed, then hitting the <RETURN> key will automatically select the button.

A *text region* is an editor like widget. This widget is brought into focus with a click of the left mouse button. To manipulate this widget, simply type in the text. Use of arrow keys, backspace/delete key, mouse selection of text for deletion or overwrite, copying and pasting with sole use of mouse buttons are permitted. This widget is usually accompanied by a scrollbar for vertically scanning a long entry.

5.9 `xpbs` X-Windows Preferences

The resources that can be set in the X resources file, `~/.xpbsrc`, are:

*serverHosts	list of Server hosts (space separated) to query by `xpbs`. A special keyword **PBS_DEFAULT_SERVER** can be used which will be used as a placeholder for the value obtained from the `/etc/pbs.conf` file.
*timeoutSecs	specify the number of seconds before timing out waiting for a connection to a PBS host.
*xtermCmd	the xterm command to run driving an interactive PBS session.
*labelFont	font applied to text appearing in labels.

*fixlabelFont	font applied to text that label fixed-width widgets such as list-box labels. This must be a fixed-width font.
*textFont	font applied to a text widget. Keep this as fixed-width font.
*backgroundColor	the color applied to background of frames, buttons, entries, scrollbar handles.
*foregroundColor	the color applied to text in any context.
*activeColor	the color applied to the background of a selection, a selected command button, or a selected scroll bar handle.
*disabledColor	color applied to a disabled widget.
*signalColor	color applied to buttons that signal something to the user about a change of state. For example, the color of the *Track Job* button when returned output files are detected.
*shadingColor	a color shading applied to some of the frames to emphasize focus as well as decoration.
*selectorColor	the color applied to the selector box of a radiobutton or check-button.
*selectHosts	list of hosts (space separated) to automatically select/highlight in the HOSTS listbox.
*selectQueues	list of queues (space separated) to automatically select/highlight in the QUEUES listbox.
*selectJobs	list of jobs (space separated) to automatically select/highlight in the JOBS listbox.
*selectOwners	list of owners checked when limiting the jobs appearing on the Jobs listbox in the main xpbs window. Specify value as "Owners: <list_of_owners>". See -u option in qselect(1B) for format of <list_of_owners>.
*selectStates	list of job states to look for (do not space separate) when limiting the jobs appearing on the Jobs listbox in the main xpbs window. Specify value as "Job_States: <states_string>". See -s option in qselect(1B) for format of <states_string>.
*selectRes	list of resource amounts (space separated) to consult when limiting the jobs appearing on the Jobs listbox in the main xpbs window. Specify value as "Resources: <res_string>". See -l option in qselect(1B) for format of <res_string>.
*selectExecTime	the Execution Time attribute to consult when limiting the list of jobs appearing on the Jobs listbox in the main xpbs window. Specify value as "Queue_Time: <exec_time>". See -a option in qselect(1B) for format of <exec_time>.
*selectAcctName	the name of the account that will be checked when limiting the

	jobs appearing on the Jobs listbox in the main xpbs window. Specify value as "Account_Name: <account_name>". See -A option in qselect(1B) for format of <account_name>.
*selectCheckpoint	the checkpoint attribute relationship (including the logical operator) to consult when limiting the list of jobs appearing on the Jobs listbox in the main xpbs window. Specify value as "Checkpoint: <checkpoint_arg>". See -c option in qselect(1B) for format of <checkpoint_arg>.
*selectHold	the hold types string to look for in a job when limiting the jobs appearing on the Jobs listbox in the main xpbs window. Specify value as "Hold_Types: <hold_string>". See -h option in qselect(1B) for format of <hold_string>.
*selectPriority	the priority relationship (including the logical operator) to consult when limiting the list of jobs appearing on the Jobs listbox in the main xpbs window. Specify value as "Priority: <priority_value>". See -p option in qselect(1B) for format of <priority_value>.
*selectRerun	the rerunnable attribute to consult when limiting the list of jobs appearing on the Jobs listbox in the main xpbs window. Specify value as "Rerunnable: <rerun_val>". See -r option in qselect(1B) for format of <rerun_val>.
*selectJobName	name of the job that will be checked when limiting the jobs appearing on the Jobs listbox in the main xpbs window. Specify value as "Job_Name: <jobname>". See -N option in qselect(1B) for format of <jobname>.
*iconizeHostsView	a boolean value (true or false) indicating whether or not to iconize the HOSTS region.
*iconizeQueuesView	a boolean value (true or false) indicating whether or not to iconize the QUEUES region.
*iconizeJobsView	a boolean value (true or false) indicating whether or not to iconize the JOBS region.
*iconizeInfoView	a boolean value (true or false) indicating whether or not to iconize the INFO region.
*jobResourceList	a curly-braced list of resource names as according to architecture known to xpbs. The format is as follows: { <arch-type1> resname1 resname2 ... resnameN } { <arch-type2> resname1 resname2 ... resnameN } { <arch-typeN> resname1 resname2 ... resnameN }

Chapter 6

Checking Job / System Status

This chapter introduces several PBS commands useful for checking status of jobs, queues, and PBS Servers. Examples for use are included, as are instructions on how to accomplish the same task using the `xpbs` graphical interface.

6.1 The `qstat` Command

The **`qstat`** command is used to the request the status of jobs, queues, and the PBS Server. The requested status is written to standard output stream (usually the user's terminal). When requesting job status, any jobs for which the user does not have view privilege are not displayed.

6.1.1 Checking Job Status

Executing the `qstat` command without any options displays job information in the default format. (An alternative display format is also provided, and is discussed below.) The default display includes the following information:

> The job identifier assigned by PBS
> The job name given by the submitter
> The job owner
> The CPU time used

The job state
The queue in which the job resides

The job state is abbreviated to a single character:

E   Job is exiting after having run
H   Job is held
Q   Job is queued, eligible to run or be routed
R   Job is running
T   Job is in transition (being moved to a new location)
W   Job is waiting for its requested execution time to be reached or
     job specified a stage-in request which failed for some reason.
S   Job is suspended

The following example illustrates the default display of `qstat`.

```
% qstat
Job id     Name         User          Time Use S Queue
---------  -----------  -----------  -------- - -----
16.south   aims14       james               0 H workq
18.south   aims14       james               0 W workq
26.south   airfoil      barry        00:21:03 R workq
27.south   airfoil      barry        21:09:12 R workq
28.south   subrun       james               0 Q workq
29.south   tns3d        susan               0 Q workq
30.south   airfoil      barry               0 Q workq
31.south   seq_35_3     bayuca              0 Q workq
```

An alternative display (accessed via the "-a" option) is also provided that includes extra information about jobs, including the following additional fields:

Session ID
Number of nodes requested
Number of parallel tasks (or CPUs)
Requested amount of memory
Requested amount of wallclock time
Elapsed time in the current job state.

```
% qstat -a
                                    Req'd       Elap
Job ID    User    Queue Jobname Sess NDS TSK Mem Time S Time
--------  ------  ----- ------- ---- --- --- --- ---- - ----
16.south  james   workq aims14  --   --   1  -- 0:01 H  --
18.south  james   workq aims14  --   --   1  -- 0:01 W  --
51.south  barry   workq airfoil 930  --   1  -- 0:13 R 0:01
52.south  james   workq subrun  --   --   1  -- 0:10 Q  --
53.south  susan   workq tns3d   --   --   1  -- 0:20 Q  --
54.south  barry   workq airfoil --   --   1  -- 0:13 Q  --
55.south  bayuca  workq seq_35_ --   --   1  -- 2:00 Q  --
```

Other options which utilize the alternative display are discussed in subsequent sections of this chapter.

6.1.2 Viewing Specific Information

When requesting queue or Server status `qstat` will output information about each destination. The various options to `qstat` take as an operand either a job identifier or a destination. If the operand is a job identifier, it must be in the following form:

> `sequence_number[.server_name][@server]`

where `sequence_number.server_name` is the job identifier assigned at submittal time, see `qsub`. If the `.server_name` is omitted, the name of the default Server will be used. If `@server` is supplied, the request will be for the job identifier currently at that Server.

If the operand is a destination identifier, it takes one of the following three forms:

> `queue`
> `@server`
> `queue@server`

If `queue` is specified, the request is for status of all jobs in that queue at the default Server. If the `@server` form is given, the request is for status of all jobs at that Server. If a full destination identifier, `queue@server`, is given, the request is for status of all jobs in the named `queue` at the named `server`.

> **Important:**   If a PBS Server is not specified on the `qstat` command line, the default Server will be used. (See discussion of **PBS_DEFAULT** in "Environment Variables" on page 21.)

6.1.3 Checking Server Status

The "**-B**" option to `qstat` displays the status of the specified PBS Batch Server. One line of output is generated for each Server queried. The three letter abbreviations correspond to various job limits and counts as follows: Maximum, Total, Queued, Running, Held, Waiting, Transiting, and Exiting. The last column gives the status of the Server itself: active, idle, or scheduling.

```
% qstat -B
Server       Max  Tot  Que  Run  Hld  Wat  Trn  Ext Status
-----------  ---  ---- ---- ---- ---- ---- ---- ---- ------
fast.pbspro   0   14   13    1    0    0    0    0 Active
```

When querying jobs, Servers, or queues, you can add the "-f" option to `qstat` to change the display to the *full* or *long* display. For example, the Server status shown above would be expanded using "-f" as shown below:

```
% qstat -Bf
Server: fast.pbspro.com
    server_state = Active
    scheduling = True
    total_jobs = 14
    state_count = Transit:0 Queued:13 Held:0 Waiting:0
                  Running:1 Exiting:0
    managers = james@fast.pbspro.com
    default_queue = workq
    log_events = 511
    mail_from = adm
    query_other_jobs = True
    resources_available.mem = 64mb
    resources_available.ncpus = 2
    resources_default.ncpus = 1
    resources_assigned.ncpus = 1
    resources_assigned.nodect = 1
    scheduler_iteration = 600
    pbs_version = PBSPro_5_2_1
```

6.1.4 Checking Queue Status

The "**-Q**" option to `qstat` displays the status of all (or any specified) queues at the (optionally specified) PBS Server. One line of output is generated for each queue queried. The three letter abbreviations correspond to limits, queue states, and job counts as follows: Maximum, Total, Enabled Status, Started Status, Queued, Running, Held, Waiting, Transiting, and Exiting. The last column gives the type of the queue: *routing* or *execution*.

```
% qstat -Q

Queue Max Tot Ena Str Que Run Hld Wat Trn Ext Type
----- --- --- --- --- --- --- --- --- --- --- ---------
workq   0  10 yes yes   7   1   1   1   0   0 Execution
```

The full display for a queue provides additional information:

```
% qstat -Qf
Queue: workq
     queue_type = Execution
     total_jobs = 10
     state_count = Transit:0 Queued:7 Held:1 Waiting:1
                   Running:1 Exiting:0
     resources_assigned.ncpus = 1
     hasnodes = False
     enabled = True
     started = True
```

6.1.5 Viewing Job Information

We saw above that the "`-f`" option could be used to display full or long information for queues and Servers. The same applies to jobs. By specifying the "`-f`" option and a job identifier, PBS will print all information known about the job (e.g. resources requested, resource limits, owner, source, destination, queue, etc.) as shown in the following example. (See "Job Attributes" on page 45 for a description of attribute.)

```
% qstat -f 89
Job Id: 89.south
    Job_Name = tns3d
    Job_Owner = susan@south.pbspro.com
    resources_used.cput = 00:00:00
    resources_used.mem = 2700kb
    resources_used.ncpus = 1
    resources_used.vmem = 5500kb
    resources_used.walltime = 00:00:00
    job_state = R
    queue = workq
    server = south
    Checkpoint = u
    ctime = Thu Aug 23 10:11:09 2003
    Error_Path = south:/u/susan/tns3d.e89
    exec_host = south/0
    Hold_Types = n
    Join_Path = oe
    Keep_Files = n
    Mail_Points = a
    mtime = Thu Aug 23 10:41:07 2003
    Output_Path = south:/u/susan/tns3d.o89
    Priority = 0
    qtime = Thu Aug 23 10:11:09 2003
    Rerunable = True
    Resource_List.mem = 300mb
    Resource_List.ncpus = 1
    Resource_List.walltime = 00:20:00
    session_id = 2083
    Variable_List = PBS_O_HOME=/u/susan,PBS_O_LANG=en_US,
        PBS_O_LOGNAME=susan,PBS_O_PATH=/bin:/usr/bin,
        PBS_O_SHELL=/bin/csh,PBS_O_HOST=south,
        PBS_O_WORKDIR=/u/susan,PBS_O_SYSTEM=Linux,
        PBS_O_QUEUE=workq
    euser = susan
    egroup = mrj
    queue_type = E
    comment = Job run on node south - started at 10:41
    etime = Thu Aug 23 10:11:09 2003
```

6.1.6 List User-Specific Jobs

The "**-u**" option to qstat displays jobs owned by any of a list of user names specified. The syntax of the list of users is:

```
user_name[@host][,user_name[@host],...]
```

Host names are not required, and may be "wild carded" on the left end, e.g. "*.pbspro.com". *user_name* without a "@host" is equivalent to "user_name@*", that is at any host.

```
% qstat -u james

                                     Req'd      Elap
Job ID    User    Queue Jobname Sess NDS TSK Mem Time S Time
-------- ------ ----- ------- ---- --- --- --- ---- - ----
16.south james  workq aims14   --    --   1  -- 0:01 H  --
18.south james  workq aims14   --    --   1  -- 0:01 W  --
52.south james  workq subrun   --    --   1  -- 0:10 Q  --

% qstat -u james,barry

51.south barry  workq airfoil 930    --   1  -- 0:13 R 0:01
52.south james  workq subrun   --    --   1  -- 0:10 Q  --
54.south barry  workq airfoil  --    --   1  -- 0:13 Q  --
```

6.1.7 List Running Jobs

The "**-r**" option to qstat displays the status of all running jobs at the (optionally specified) PBS Server. Running jobs include those that are running and suspended. One line of output is generated for each job reported, and the information is presented in the alternative display.

6.1.8 List Non-Running Jobs

The "**-i**" option to qstat displays the status of all non-running jobs at the (optionally specified) PBS Server. Non-running jobs include those that are queued, held, and waiting. One line of output is generated for each job reported, and the information is presented in the alternative display (see description above).

6.1.9 Display Size in Gigabytes

The "**-G**" option to qstat displays all jobs at the requested (or default) Server using the alternative display, showing all size information in gigabytes (GB) rather than the default of smallest displayable units. Note that if the size specified is less than 1 GB, then the amount if rounded up to 1 GB.

6.1.10 Display Size in Megawords

The "**-M**" option to qstat displays all jobs at the requested (or default) Server using the alternative display, showing all size information in megawords (MW) rather than the default of smallest displayable units. A word is considered to be 8 bytes.

6.1.11 List Nodes Assigned to Jobs

The "**-n**" option to qstat displays the nodes allocated to any running job at the (optionally specified) PBS Server, in addition to the other information presented in the alternative display. The node information is printed immediately below the job (see job 51 in the example below), and includes the node name and number of virtual processors assigned to the job (i.e. "south/0", where "south" is the node name, followed by the virtual processor(s) assigned.). A text string of "--" is printed for non-running jobs. Notice the differences between the queued and running jobs in the example below:

```
% qstat -n
                                       Req'd      Elap
Job ID    User    Queue Jobname Sess NDS TSK Mem Time S Time
--------  ------  ----- ------- ---- --- --- --- ---- - ----
16.south james   workq aims14   --   --   1  -- 0:01 H  --
    --
18.south james   workq aims14   --   --   1  -- 0:01 W  --
    --
51.south barry   workq airfoil  930  --   1  -- 0:13 R 0:01
    south/0
52.south james   workq subrun   --   --   1  -- 0:10 Q  --
    --
```

6.1.12 Display Job Comments

The "**-s**" option to qstat displays the job comments, in addition to the other information presented in the alternative display. The job comment is printed immediately below

the job. By default the job comment is updated by the Scheduler with the reason why a given job is not running, or when the job began executing. A text string of "--" is printed for jobs whose comment has not yet been set. The example below illustrates the different type of messages that may be displayed:

```
% qstat -s
                                         Req'd      Elap
Job ID    User    Queue Jobname Sess NDS TSK Mem Time S Time
-------- ------ ----- ------- ---- --- --- --- ---- - ----
16.south james  workq aims14   --    --   1  -- 0:01 H  --
     Job held by james on Wed Aug 22 13:06:11 2001
18.south james  workq aims14   --    --   1  -- 0:01 W  --
     Waiting on user requested start time
51.south barry  workq airfoil  930   --   1  -- 0:13 R 0:01
     Job run on node south - started Thu Aug 23 at 10:56

     --
```

6.1.13 Display Queue Limits

The "**-q**" option to qstat displays any limits set on the requested (or default) queues. Since PBS is shipped with no queue limits set, any visible limits will be site-specific. The limits are listed in the format shown below.

```
% qstat -q
server: south

Queue   Memory CPU Time Walltime Node Run Que Lm  State
------ ------ -------- -------- ---- --- --- --  -----
workq    --      --       --      --   1   8 --   E R
```

6.2 Viewing Job / System Status with xpbs

The main display of xpbs shows a brief listing of all selected Servers, all queues on those Servers, and any jobs in those queues that match the *selection criteria* (discussed below). Servers are listed in the HOST panel near the top of the display.

To view detailed information about a given Server (i.e. similar to that produced by "qstat -fB") select the Server in question, then click the *Detail* button. Likewise, for details on a given queue (i.e. similar to that produced by "qstat -fQ") select the queue in question, then click its corresponding *Detail* button. The same applies for jobs as well (i.e. "qstat -f"). You can view detailed information on any displayed job by selecting it, and then clicking on the *Detail* button. Note that the list of jobs displayed will be dependent upon the Selection Criteria currently selected. This is discussed in the xpbs portion of the next section.

6.3 The `qselect` Command

The **qselect** command provides a method to list the job identifier of those jobs which meet a list of selection criteria. Jobs are selected from those owned by a single Server. When qselect successfully completes, it will have written to standard output a list of zero or more job identifiers which meet the criteria specified by the options. Each option acts as a filter restricting the number of jobs which might be listed. With no options, the qselect command will list all jobs at the Server which the user is authorized to list (query status of). The -u option may be used to limit the selection to jobs owned by this user or other specified users.

When an option is specified with a optional op component to the option argument, then op specifies a relation between the value of a certain job attribute and the value component of the option argument. If an op is allowable on an option, then the description of the option letter will indicate the op is allowable. The only acceptable strings for the op component, and the relation the string indicates, are shown in the following list:

.eq.	The value represented by the attribute of the job is equal to the value represented by the option argument.
.ne.	The value represented by the attribute of the job is not equal to the value represented by the option argument.
.ge.	The value represented by the attribute of the job is greater than or equal to the value represented by the option argument.
.gt.	The value represented by the attribute of the job is greater than the value represented by the option argument.
.le.	The value represented by the attribute of the job is less than or equal to the value represented by the option argument.
.lt.	The value represented by the attribute of the job is less than the value represented by the option argument.

The available options to `qselect` are:

-a [op]date_time   Restricts selection to a specific time, or a range of times. The `qselect` command selects only jobs for which the value of the *Execution_Time* attribute is related to the *date_time* argument by the optional *op* operator. The *date_time* argument is in the POSIX date format:

`[[CC]YY]MMDDhhmm[.SS]`

where the `MM` is the two digits for the month, `DD` is the day of the month, `hh` is the hour, `mm` is the minute, and the optional `SS` is the seconds. `CC` is the century and `YY` the year. If op is not specified, jobs will be selected for which the *Execution_Time* and *date_time* values are equal.

-A account_string   Restricts selection to jobs whose *Account_Name* attribute matches the specified account_string.

-c [op] interval   Restricts selection to jobs whose *Checkpoint* interval attribute matches the specified relationship. The values of the *Checkpoint* attribute are defined to have the following ordered relationship:

`n > s > c=minutes > c > u`

If the optional op is not specified, jobs will be selected whose *Checkpoint* attribute is equal to the interval argument.

-h hold_list   Restricts the selection of jobs to those with a specific set of hold types. Only those jobs will be selected whose *Hold_Types* attribute exactly match the value of the *hold_list* argument. The *hold_list* argument is a string consisting of one or more occurrences the single letter n, or one or more of the letters u, o, or s in any combination. If letters are duplicated, they are treated as if they occurred once. The letters represent the hold types:

Letter	Meaning
n	none
u	user
o	operator
s	system

-l resource_list   Restricts selection of jobs to those with specified resource amounts. Only those jobs will be selected whose *Resource_List* attribute matches the specified relation with each resource and value listed in the *resource_list* argument. The relation operator op **must** be present. The *resource_list* is in the following format:

```
resource_nameopvalue[,resource_nameopval,...]
```

-N name   Restricts selection of jobs to those with a specific name.

-p [op]priority   Restricts selection of jobs to those with a priority that matches the specified relationship. If op is not specified, jobs are selected for which the job Priority attribute is equal to the priority.

-q destination   Restricts selection to those jobs residing at the specified destination. The destination may be one of the following three forms:

```
queue
@server
queue@server
```

If the -q option is not specified, jobs will be selected from the default Server. If the destination describes only a queue, only jobs in that queue on the default batch Server will be selected. If the destination describes only a Server, then jobs in all queues on that Server will be selected. If the destination describes both a queue and a Server, then only jobs in the named queue on the named Server will be selected.

-r rerun   Restricts selection of jobs to those with the specified *Rerunable* attribute. The option argument must be a single character. The following two characters are supported by PBS: `y` and `n`.

-s states   Restricts job selection to those in the specified states. The *states* argument is a character string which consists of any combination of the characters: `E`, `H`, `Q`, `R`, `S`, `T`, `U`, and `W`. The characters in the *states* argument have the following interpretation:

Table 9: Job States Viewable by Users

State	Meaning
E	Job is in the process of Exiting.
H	Job has been placed on Hold.
Q	Job is in the Queued state.
R	Job is in the Running state.
S	Job has been Suspended.
T	Job is Transiting between states.
U	Job suspended due to workstation user activity
W	Job is in the Waiting state.

Jobs will be selected which are in any of the specified *states*.

-u user_list   Restricts selection to jobs owned by the specified user names. This provides a means of limiting the selection to jobs owned by one or more users. The syntax of the *user_list* is:

```
user_name[@host][,user_name[@host],...]
```

Host names may be wild carded on the left end, e.g. "`*.pbspro.com`". *User_name* without a "`@host`" is equivalent to "`user_name@*`", i.e. at any host. Jobs will be selected which are owned by the listed users at the corresponding hosts.

For example, say you want to list all jobs owned by user "barry" that requested more than 16 CPUs. You could use the following `qselect` command syntax:

```
% qselect -u barry -l ncpus.gt.16
121.south
133.south
154.south
```

Notice that what is returned is the job identifiers of jobs that match the selection criteria. This may or may not be enough information for your purposes. Many users will use UNIX shell syntax to pass the list of job identifiers directly into `qstat` for viewing purposes, as shown in the next example.

```
% qstat -a  ` qselect -u barry -l ncpus.gt.16 `
                                      Req'd      Elap
Job ID      User   Queue Jobname Sess NDS TSK Mem Time S Time
--------   ----- ----- ------- ---- --- --- --- ---- - ----
121.south barry workq airfoil  --    --   32  -- 0:01 H   --
133.south barry workq trialx   --    --   20  -- 0:01 W   --
154.south barry workq airfoil 930    --   32  -- 1:30 R 0:32
```

Note: This technique of using the output of the `qselect` command as input to `qstat` can also be used to supply input to other PBS commands as well.

6.4 Selecting Jobs Using xpbs

The `xpbs` command provides a graphical means of specifying job selection criteria, offering the flexibility of the `qselect` command in a point and click interface. Above the JOBS panel in the main `xpbs` display is the *Other Criteria* button. Clicking it will bring up a menu that lets you choose and select any job selection criteria you wish.

The example below shows a user clicking on the *Other Criteria* button, then selecting *Job States*, to reveal that all job states are currently selected. Clicking on any of these job states would remove that state from the selection criteria.
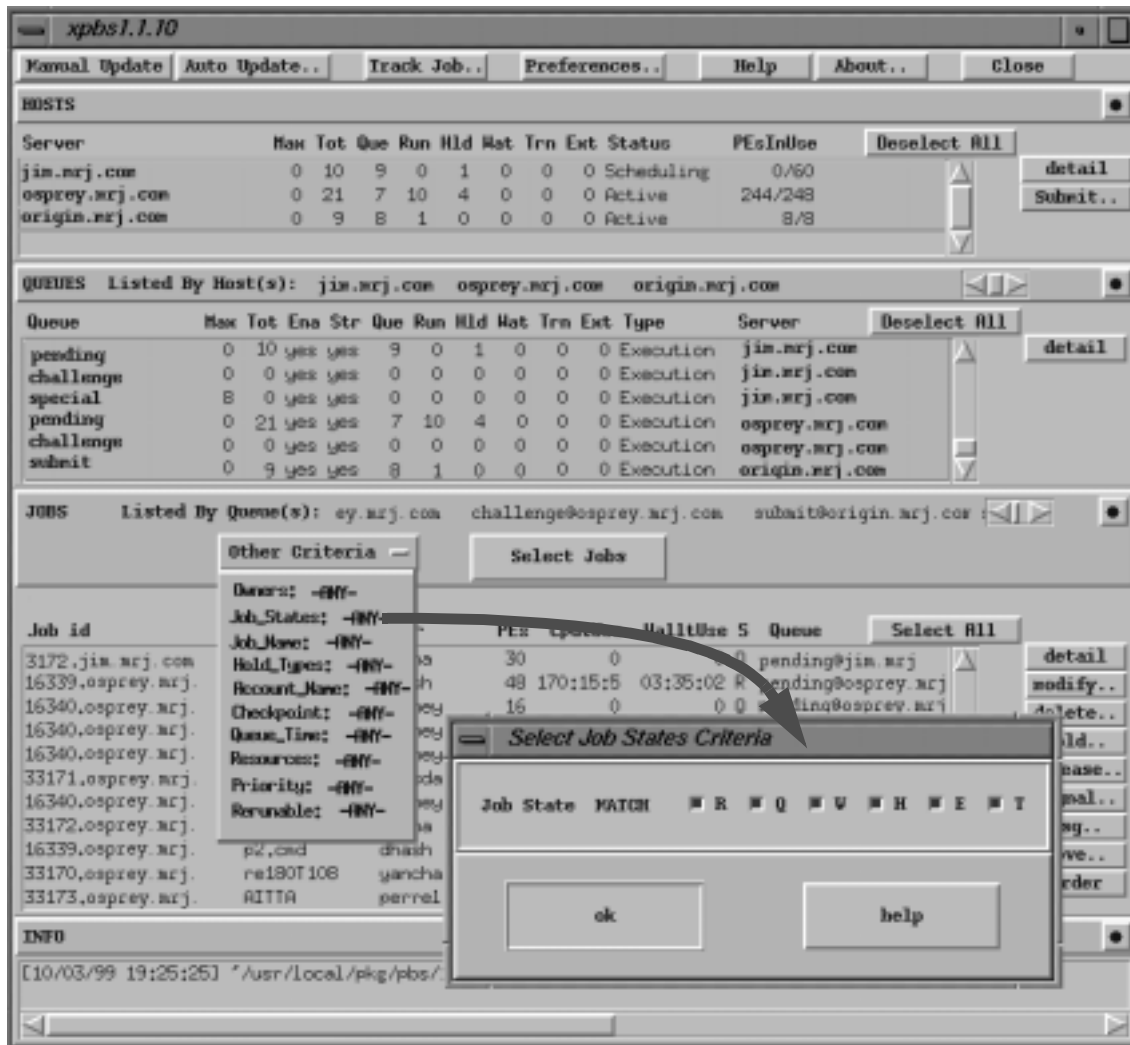

You may specify as many or as few selection criteria as you wish. When you have completed your selection, click on the *Select Jobs* button above the HOSTS panel to have xpbs refresh the display with the jobs that match your selection criteria. The selected criteria will remain in effect until you change them again. If you exit xpbs, you will be prompted if you wish to save your configuration information; this includes the job selection criteria.

6.5 Using `xpbs` TrackJob Feature

The `xpbs` command includes a feature that allows you to track the progress of your jobs. When you enable the *Track Job* feature, `xpbs` will monitor your jobs, looking for the output files that signal completion of the job. The *Track Job* button will flash red on the `xpbs` main display, and if you then click it, `xpbs` will display a list of all completed jobs (that you were previously tracking). Selecting one of those jobs will launch a window containing the standard output and standard error files associated with the job.

To enable `xpbs` job tracking, click on the *Track Job* button at the top center of the main `xpbs` display. Doing so will bring up the Track Job dialog box shown below.
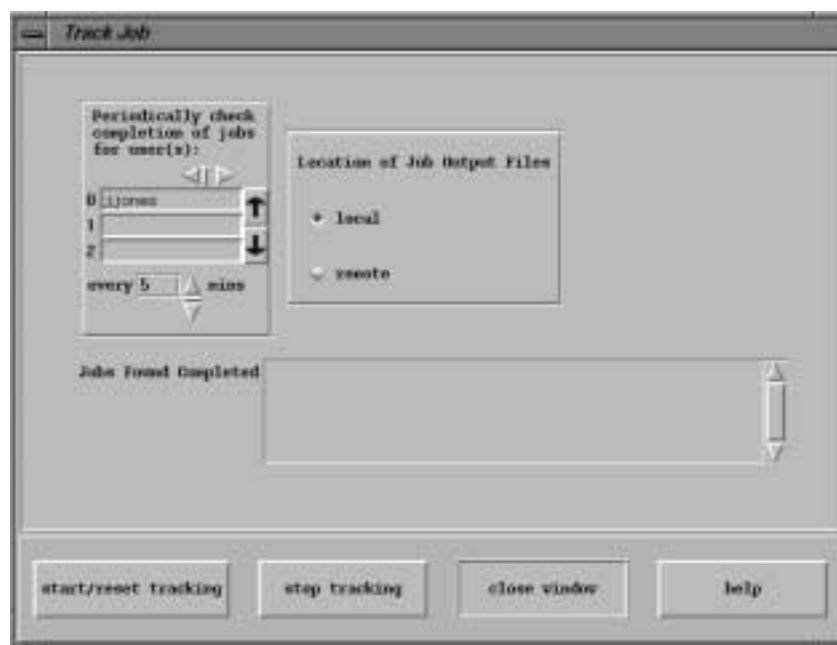

From this window you can name the users whose jobs you wish to monitor. You also need to specify where you expect the output files to be: either local or remote (e.g. will the files be retained on the Server host, or did you request them to be delivered to another host?). Next, click the *start/reset tracking button* and then the *close window* button. Note that you can disable job tracking at any time by clicking the *Track Job* button on the main `xpbs` display, and then clicking the *stop tracking* button.

Chapter 7

Working With PBS Jobs

This chapter introduces the reader to various commands useful in working with PBS jobs. Covered topics include: modifying job attributes, holding and releasing jobs, sending messages to jobs, changing order of jobs within a queue, sending signals to jobs, and deleting jobs. In each section below, the command line method for accomplishing a particular task is presented first, followed by the `xpbs` method.

7.1 Modifying Job Attributes

There may come a time when you need to change an attribute on a job you have already submitted. Perhaps you made a mistake on the resource requirements, or perhaps a previous job ran out of time, so you want to add more time to a queued job before it starts running. Whatever the reason, PBS provides the **`qalter`** command.

Most attributes can be changed by the owner of the job while the job is still queued. However, once a job begins execution, the resource limits cannot be changed. These include:

> cputime
> walltime
> number of CPUs
> memory

The usage syntax for `qalter` is:

```
qalter job-resources job-list
```

The *job-resources* are the same option and value pairs used on the `qsub` command line. (See "Submitting a PBS Job" on page 24.) Only those attributes listed as options on the command will be modified. If any of the specified attributes cannot be modified for a job for any reason, none of that job's attributes will be modified.

The following examples illustrate how to use the `qalter` command. First we list all the jobs of a particular user. Then we modify two attributes as shown (increasing the wall-clock time from 13 to 20 minutes, and changing the job name from "airfoil" to "engine"):

```
% qstat -u barry
                                         Req'd    Elap
Job ID    User    Queue Jobname Sess NDS TSK Mem Time S Time
--------  ------  ----- ------- ---- --- --- --- ---- - ----
51.south barry   workq airfoil  930  --   1  -- 0:13 R 0:01
54.south barry   workq airfoil  --   --   1  -- 0:13 Q  --

% qalter -l walltime=20:00 -N engine 54

% qstat -a 54
                                         Req'd    Elap
Job ID    User    Queue Jobname Sess NDS TSK Mem Time S Time
--------  ------  ----- ------- ---- --- --- --- ---- - ----
54.south barry   workq engine   --   --   1  -- 0:20 Q  --
```

To alter a job attribute via `xpbs`, first select the job(s) of interest, and the click on *modify* button. Doing so will bring up the *Modify Job Attributes* dialog box. From this window you may set the new values for any attribute you are permitted to change. Then click on the *confirm modify* button at the lower left of the widow.

7.2 Deleting Jobs

PBS provides the **qdel** command for deleting jobs from the system. The `qdel` command deletes jobs in the order in which their job identifiers are presented to the command. A job that has been deleted is no longer subject to management by PBS. A batch job may be deleted by its owner, a PBS operator, or a PBS administrator.

```
% qdel 17
```

To delete a job using xpbs, first select the job(s) of interest, then click the *delete* button.

7.3 Holding and Releasing Jobs

PBS provides a pair of commands to hold and release jobs. To hold a job is to mark it as ineligible to run until the hold on the job is "released".

The **qhold** command requests that a Server place one or more holds on a job. A job that has a hold is not eligible for execution. There are three types of holds: *user*, *operator*, and *system*. A user may place a *user* hold upon any job the user owns. An "operator", who is a user with "operator privilege", may place either an *user* or an *operator* hold on any job. The PBS Manager may place any hold on any job. The usage syntax of the qhold command is:

```
qhold [ -h hold_list ] job_identifier ...
```

The *hold_list* defines the type of holds to be placed on the job. The *hold_list* argument is a string consisting of one or more of the letters u, o, or s in any combination, or the letter n. The hold type associated with each letter is:

Letter	Meaning
n	none
u	user
o	operator
s	system

If no -h option is given, the *user* hold will be applied to the jobs described by the *job_identifier* operand list. If the job identified by *job_identifier* is in the queued, held, or waiting states, then all that occurs is that the hold type is added to the job. The job is then placed into held state if it resides in an execution queue.

If the job is in running state, then the following additional action is taken to interrupt the execution of the job. If checkpoint / restart is supported by the host system, requesting a hold on a running job will cause (1) the job to be checkpointed, (2) the resources assigned to the job to be released, and (3) the job to be placed in the held state in the execution queue. If checkpoint / restart is not supported, qhold will only set the requested hold attribute. This will have no effect unless the job is requeued with the qrerun command.

Similarly, the **qrls** command releases a hold on a job. However, the user executing the qrls command must have the necessary privilege to release a given hold. The same rules apply for releasing a hold as exist for setting a hold.

The usage syntax of the qrls command is:

```
qrls [ -h hold_list ] job_identifier ...
```

The following examples illustrate how to use both the qhold and qrls commands. Notice that the state ("S") column shows how the state of the job changes with the use of these two commands.

```
% qstat -a 54
                                       Req'd      Elap
Job ID    User   Queue Jobname Sess NDS TSK Mem Time S Time
--------  ------ ----- ------- ---- --- --- --- ---- - ----
54.south barry  workq  engine  --   --   1  -- 0:20 Q   --

% qhold 54
% qstat -a 54
                                       Req'd      Elap
Job ID    User   Queue Jobname Sess NDS TSK Mem Time S Time
--------  ------ ----- ------- ---- --- --- --- ---- - ----
54.south barry  workq  engine  --   --   1  -- 0:20 H   --

% qrls -h u 54
% qstat -a 54
                                       Req'd      Elap
Job ID    User   Queue Jobname Sess NDS TSK Mem Time S Time
--------  ------ ----- ------- ---- --- --- --- ---- - ----
54.south barry  workq  engine  --   --   1  -- 0:20 Q   --
```

If you attempted to release a hold on a job which is not on hold, the request will be ignored. If you use the qrls command to release a hold on a job that had been previously

running, and subsequently checkpointed, the hold will be released, and the job will return to the queued (Q) state (and be eligible to be scheduled to run when resources come available).

To hold (or release) a job using xpbs, first select the job(s) of interest, then click the *hold* (or *release*) button.

7.4 Sending Messages to Jobs

To send a message to a job is to write a message string into one or more output files of the job. Typically this is done to leave an informative message in the output of the job. Such messages can be written using the **qmsg** command.

> **Important:** A message can only be sent to running jobs.

The usage syntax of the qmsg command is:

```
qmsg [ -E ][ -O ] message_string job_identifier
```

The -E option writes the message into the error file of the specified job(s). The -O option writes the message into the output file of the specified job(s). If neither option is specified, the message will be written to the error file of the job.

The first operand, *message_string*, is the message to be written. If the string contains blanks, the string must be quoted. If the final character of the string is not a newline, a newline character will be added when written to the job's file. All remaining operands are *job_identifiers* which specify the jobs to receive the message string. For example:

```
% qmsg -E "hello to my error (.e) file" 55
% qmsg -O "hello to my output (.o) file" 55
% qmsg "this too will go to my error (.e) file" 55
```

To send a message to a job using xpbs, first select the job(s) of interest, then click the *msg* button. Doing so will launch the *Send Message to Job* dialog box, as shown below. From this window, you may enter the message you wish to send and indicate whether it should be written to the standard output or the standard error file of the job. Click the *Send Message* button to complete the process.
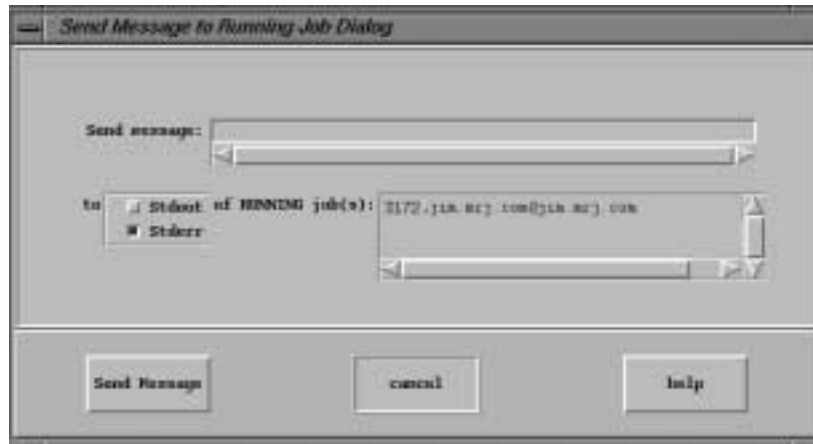

7.5 Sending Signals to Jobs

The **qsig** command requests that a signal be sent to executing PBS jobs. The signal is sent to the session leader of the job. Usage syntax of the qsig command is:

    qsig [-s signal] job_identifier

If the -s option is not specified, SIGTERM is sent. If the -s option is specified, it declares which *signal* is sent to the job. The *signal* argument is either a signal name, e.g. SIGKILL, the signal name without the SIG prefix, e.g. KILL, or a unsigned signal number, e.g. 9. The signal name SIGNULL is allowed; the Server will send the signal 0 to the job which will have no effect. Not all signal names will be recognized by qsig. If it doesn't recognize the signal name, try issuing the signal number instead. The request to signal a batch job will be rejected if:

> The user is not authorized to signal the job.
> The job is not in the running state.
> The requested signal is not supported by the execution host.
> The job is exiting.

Two special signal names, "suspend" and "resume", (note, all lower case), are used to suspend and resume jobs. When suspended, a job continues to occupy system resources but is not executing and is not charged for walltime. Manager or operator privilege is required to suspend or resume a job.

The three examples below all send a signal 9 (SIGKILL) to job 34:

```
% qsig -s SIGKILL 34
% qsig -s KILL 34
% qsig -s 9 34
```

Important: On most systems the command "`kill -l`" (that's 'minus ell')
will list all the available signals. The UNIX manual page for
`kill(1)` usually also lists the available signals.

To send a signal to a job using `xpbs`, first select the job(s) of interest, then click the *signal*
button. Doing so will launch the *Signal Running Job* dialog box, shown below.
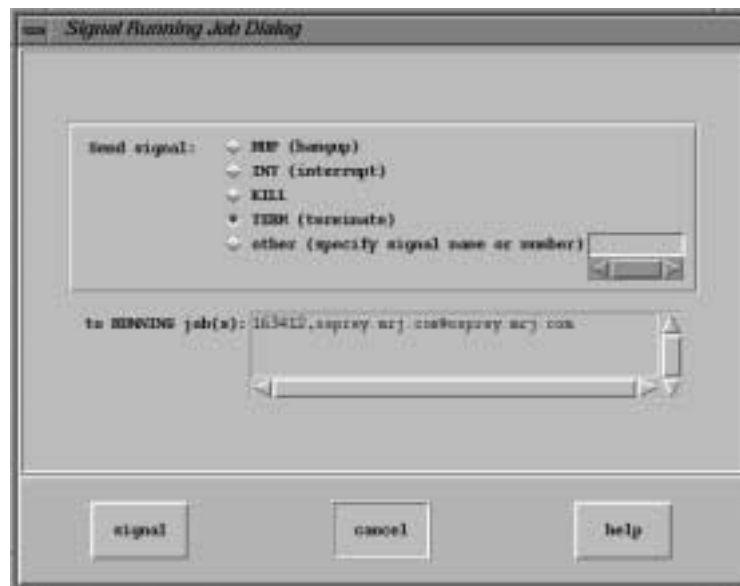

From this window, you may click on any of the common signals, or you may enter the sig-
nal number or signal name you wish to send to the job. Click the *Signal* button to complete
the process.

7.6 Changing Order of Jobs Within Queue

PBS provides the **qorder** command to change the order (or reorder) two jobs. To order
two jobs is to exchange the jobs' positions in the queue or queues in which the jobs

resides. The two jobs must be located at the same Server, and both jobs must be owned by the user. No attribute of the job (such as priority) is changed. The impact of changing the order within the queue(s) is dependent on local job scheduling policy; contact your systems administrator for details for details.

> **Important:** A job in the running state cannot be reordered.

Usage of the `qorder` command is:

        qorder job_identifier1 job_identifier2

Both operands are *job_identifiers* which specify the jobs to be exchanged.

```
% qstat -u barry

                                        Req'd     Elap
Job ID   User   Queue Jobname Sess NDS TSK Mem Time S Time
-------- ------ ----- ------- ---- --- --- --- ---- - ----
54.south barry  workq twinkie  --    --   1  -- 0:20 Q   --
63.south barry  workq airfoil  --    --   1  -- 0:13 Q   --

% qorder 54 63
% qstat -u barry

                                        Req'd     Elap
Job ID   User   Queue Jobname Sess NDS TSK Mem Time S Time
-------- ------ ----- ------- ---- --- --- --- ---- - ----
63.south barry  workq airfoil  --    --   1  -- 0:13 Q   --
54.south barry  workq twinkie  --    --   1  -- 0:20 Q   --
```

To change the order of two jobs using `xpbs`, select the two jobs, and then click the *order* button.

7.7 Moving Jobs Between Queues

PBS provides the **qmove** command to move jobs between different queues (even queues on different Servers). To move a job is to remove the job from the queue in which it resides and instantiate the job in another queue.

> **Important:** A job in the running state cannot be moved.

The usage syntax of the `qmove` command is:

```
qmove destination job_identifier(s)
```

The first operand is the new destination for

> *queue*
> @*server*
> *queue*@*server*

If the `destination` operand describes only a queue, then `qmove` will move jobs into the queue of the specified name at the job's current Server. If the `destination` operand describes only a Server, then `qmove` will move jobs into the default queue at that Server. If the `destination` operand describes both a queue and a Server, then `qmove` will move the jobs into the specified queue at the specified Server. All following operands are `job_identifiers` which specify the jobs to be moved to the new `destination`.

To move jobs between queues or between Servers using `xpbs`, select the job(s) of interest, and then click the move button. Doing so will launch the Move Job dialog box from which you can select the queue and/or Server to which you want the job(s) moved.
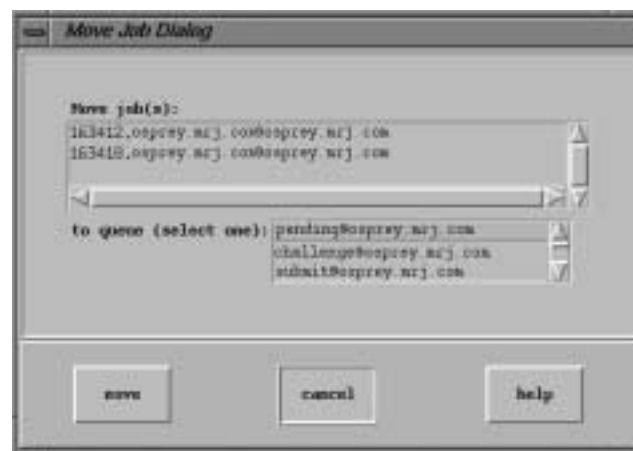

Chapter 8
Advanced PBS Features

This chapter covers the less commonly used commands and more complex topics which will add substantial functionality to your use of PBS. The reader is advised to read chapters 5 - 7 of this manual first.

8.1 Job Exit Status

The exit status of a job is normally the exit status of the shell executing the job script. If a user is using `csh` and has a `.logout` file in the home directory, the exit status of `csh` becomes the exit status of the last command in `.logout`. This may impact the use of job dependencies which depend on the job's exit status. To preserve the job's status, the user may either remove `.logout` or edit it as shown in this example:

```
set EXITVAL = $status
[previous contents remain unchanged]
exit $EXITVAL
```

Doing so will ensure that the exit status of the job persists across the invocation of the `.logout` file.

8.2 Changing Job umask

The "`-W umask=nnn`" option to `qsub` allows you to specify what `umask` PBS should use when creating and/or coping your `stdout` and `stderr` files, and any other files you direct PBS to transfer on your behalf.

The following example illustrates how to set your `umask` to 022 (i.e. to have files created with write permission for owner only: `-rw-r--r--`).

```
% qsub -W umask=022 mysubrun
```

```
#!/bin/sh
#PBS -W umask=022
...
```

8.3 Requesting qsub Wait for Job Completion

The "`-W block=true`" option to `qsub` allows you to specify that you want `qsub` to wait for the job to complete (i.e. "block") and report the exit value of the job. If job submission fails, no special processesing will take place. If the job is successfully submitted, `qsub` will block until the job terminates or an error occurs.

If `qsub` receives one of the signals: SIGHUP, SIGINT, SIGQUIT or SIGTERM, it will print a message and then exit with the exit status 2. If the job is deleted before running to completion, or an internal PBS error occurs, an error message describing the error will be printed and `qsub` will exit with an exit status of 3.

If the job runs to completion, `qsub` will exit with the exit status of the job. (See also section 8.1 "Job Exit Status" on page 93 for further discussion of the job exit status.)

8.4 Specifying Job Dependencies

PBS allows you to specify dependencies between two or more jobs. Dependencies are useful for a variety of tasks, such as:

1   Specifying the order in which jobs in a set should execute
2   Requesting a job run only if an error occurs in another job
3   Holding jobs until a particular job starts or completes execution

The "`-W depend=dependency_list`" option to `qsub` defines the dependency between multiple jobs. The *dependency_list* has the format:

```
type[:argument[:argument...][,type:argument...]
```

The *argument* is either a numeric count or a PBS job identifier according to type. If *argument* is a count, it must be greater than 0. If it is a job identifier and not fully specified in the form `seq_number.server.name`, it will be expanded according to the default Server rules which apply to job identifiers on most commands. If *argument* is null (the proceeding colon need not be specified), the dependency of the corresponding type is cleared (unset).

synccount:count	This job is the first in a set of jobs to be executed at the same time. `count` is the number of additional jobs in the set.
syncwith:jobid	This job is an additional member of a set of jobs to be executed at the same time. In the above and following dependency types, `jobid` is the job identifier of the first job in the set.

after:jobid[:jobid...]

> This job may be scheduled for execution at any point after jobs `jobid` have started execution.

afterok:jobid[:jobid...]

> This job may be scheduled for execution only after jobs `jobid` have terminated with no errors. See the `csh` warning under "User's PBS Environment" on page 18.

afternotok:jobid[:jobid...]

> This job may be scheduled for execution only after jobs `jobid` have terminated with errors. See previous `csh` warning.

afterany:jobid[:jobid...]

> This job may be scheduled for execution after jobs `jobid` have terminated, with or without errors.

on:count	This job may be scheduled for execution after `count` dependencies on other jobs have been satisfied. This form is used in conjunction with one of the before forms, see below.

before:jobid[:jobid...]

> When this job has begun execution, then jobs `jobid`... may begin.

beforeok:jobid[:jobid...]

        If this job terminates execution without errors, then jobs *jobid*... may begin. See previous `csh` warning.

beforenotok:jobid[:jobid...]

        If this job terminates execution with errors, then jobs *jobid*... may begin. See previous `csh` warning.

beforeany:jobid[:jobid...]

        When this job terminates execution, jobs *jobid*... may begin. If any of the before forms are used, the jobs referenced by *jobid* must have been submitted with a dependency type of on. If any of the before forms are used, the jobs referenced by *jobid* must have the same owner as the job being submitted. Otherwise, the dependency is ignored.

Error processing of the existence, state, or condition of the job on which the newly submitted job depends is a deferred service, i.e. the check is performed after the job is queued. If an error is detected, the new job will be deleted by the Server. Mail will be sent to the job submitter stating the error.

The following examples illustrate the most common uses for job dependencies.

Suppose you have three jobs (job1, job2, and job3) and you want job3 to start *after* job1 and job2 have *ended*. The first example below illustrates the options you would use on the `qsub` command line to implement these job dependencies.

```
$ qsub job1
16394.jupiter.pbspro.com
% qsub job2
16395.jupiter.pbspro.com
% qsub -W depend=afterany:16394:16395 job3
16396.jupiter.pbspro.com
```

As another example, suppose instead you want job2 to start *only if* job1 ends with no errors (i.e. it exits with a no error status):

```
$ qsub job1
16397.jupiter.pbspro.com
% qsub -W depend=afterok:16397 job2
16396.jupiter.pbspro.com
```

You can use `xpbs` to specify job dependencies as well. On the *Submit Job* window, in the other options section (far left, center of window) click on one of the three dependency buttons: *after depend*, *before depend*, or *concurrency*. These will launch a *Dependency* window in which you will be able to set up the dependencies you wish. The *After Dependency* dialog box is shown below.
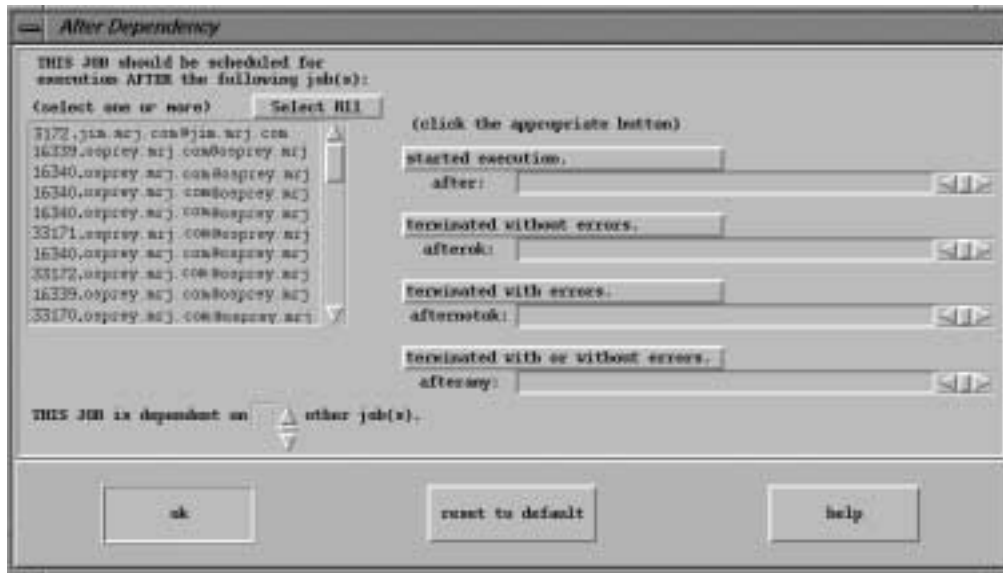

8.5 Delivery of Output Files

To transfer output files or to transfer staged-in or staged-out files to/from a remote destination, PBS uses either `rcp` or `scp` depending on the configuration options. (PBS includes a version of the `rcp(1)` command from the BSD 4.4 lite distribution, renamed `pbs_rcp`.) This version of `rcp` is provided because it, unlike some `rcp` implementations, always exits with a non-zero exits status for any error. Thus MOM knows if the file was delivered or not. Fortunately, the secure copy program, `scp`, is also based on this version of `rcp` and exits with the proper status code.

If using `rcp`, the copy of output or staged files can fail for (at least) two reasons.

1. If the user's `.cshrc` script outputs any characters to standard output, e.g. contains an echo command, `pbs_rcp` will fail.

2. The user lacks authorization to access the specified system. (See discussion in "User Authorization" on page 26.)

If using *Secure Copy (*`scp`*)*, then PBS will first try to deliver output or stage-in/out files using `scp`. If `scp` fails, PBS will try again using `rcp` (assuming that `scp` might not exist on the remote host). If `rcp` also fails, the above cycle will be repeated after a delay, in case the problem is caused by a temporary network problem. All failures are logged in MOM's log, and an email containing the errors is sent to the job owner.

For delivery of output files on the local host, PBS uses the `/bin/cp` command. Local and remote Delivery of output may fail for the following additional reasons:

1. A directory in the specified destination path does not exist.
2. A directory in the specified destination path is not searchable by the user.
3. The target directory is not writable by the user.

8.6 Input/Output File Staging

File staging is a way to specify which files should be copied onto the execution host before the job starts, and which should be copied off the execution host when it completes. (For file staging under Globus, see "PBS File Staging through GASS" on page 104.) The "`-W stagein=file_list`" and "`-W stageout=file_list`" options to `qsub` specifies which files are staged (copied) in before the job starts or staged out after the job completes execution. On completion of the job, all staged-in and staged-out files are removed from the execution system. The *file_list* is in the form:

```
local_file@hostname:remote_file[,...]
```

regardless of the direction of the copy. Note that the '@' character is used for separating the local and remote specification. The name *local_file* is the name of the file on the system where the job executes. It may be an absolute path or relative to the home directory of the user. The name *remote_file* is the destination name on the host specified by hostname. The name may be absolute or relative to the user's home directory on the destination host. Thus for stage-in, the direction of travel is:

```
local_file◀──  remote_host:remote_file
```

and for stage out, the direction of travel is:

```
local_file──▶  remote_host:remote_file
```

Note that all relative paths are relative to the user's home directory on the respective hosts. The following example shows how to stage-in a file named `grid.dat` located in the directory `/u/james` of the computer called `server`. The staged-in file is requested to be placed relative to the users home directory under the name of `dat1`.

```
#!/bin/sh
#PBS -W stagein=dat1@server:/u/james/grid.dat
...
```

PBS uses `rcp` or `scp` (or `cp` if the remote host is the local host) to perform the transfer. Hence, stage-in and stage-out are just:

```
rcp -r remote_host:remote_file local_file
rcp -r local_file remote_host:remote_file
```

As with `rcp`, the `remote_file` may be a directory name. The `local_file` specified in the stage-in/out directive may name a directory. For stage-in, if `remote_file` is a directory, then `local_file` must also be a directory. Likewise, for stage out, if `local_file` is a directory, then `remote_file` must be a directory.

If `local_file` on a stage out directive is a directory, that directory on the execution host, including all files and subdirectories, will be copied. At the end of the job, the directory, including all files and subdirectories, will be deleted. Users should be aware that this may create a problem if multiple jobs are using the same directory. The same requirements and hints discussed above in regard to delivery of output apply to staging files in and out.

Wildcards should not be used in either the `local_file` or the `remote_file` name. PBS does not expand the wildcard character on the local system. If wildcards are used in the `remote_file` name, since `rcp` is launched by `rsh` to the remote system, the expansion will occur. However, at job end, PBS will attempt to delete the file whose name actually contains the wildcard character and will fail to find it. This will leave all the staged-in files in place (undeleted).

Using `xpbs` to set up file staging directives may be easier than using the command line. On the *Submit Job* window, in the miscellany options section (far left, center of window) click on the *file staging* button. This will launch the *File Staging* dialog box (shown below) in which you will be able to set up the file staging you desire.

The *File Selection Box* will be initialized with your current working directory. If you wish to select a different directory, double-click on its name. xpbs with then list the contents of the new directory in the *File Selection Box*. When the correct directory is displayed, simply click on the name of the file you wish to stage (in or out). Its name will be written in the *File Selected* area.

Next, click either of the *Add file selected...* button to add the named file to either the stage-in or stage-out list. Doing so will write the file name into the corresponding area on the lower half of the *File Staging* window.

Now you need to provide location information. For stage-in, type in the path and filename where you want the named file placed. For stage-out, specify the hostname and pathname where you want the named file delivered.

You may repeat this process for as many files as you need to stage. When you are done selecting files, click the *OK* button.

8.7 The `pbsdsh` Command

The **pbsdsh** command allows you to distribute and execute a task to all the nodes assigned to your job by PBS. (pbsdsh uses the PBS Task Manager API, see tm(3), to distribute the program on the allocated nodes.)

Usage of the pbsdsh command is:

```
pbsdsh [-c N | -n N] [-o] [-s] [-v] command args
```

The available options are:

-c N   The program is spawned on the first *N* nodes allocated. If the value of *N* is greater than the number of nodes, it will "wrap" around, running multiple copies on the nodes. This option is mutually exclusive with -n.

-n N   The program is spawned on a single node which is the *N*-th node allocated. This option is mutual exclusive with -c.

-o   The program will not wait for the tasks to finish.

-s   If this option is given, the program is run sequentially on each node, one after the other.

-v   Verbose output about error messages and task exit status is produced.

When run without the -c or the -n option, pbsdsh will spawn the program on all nodes allocated to the PBS job. The execution take place concurrently--all copies of the task execute at (about) the same time.

The following example shows the pbsdsh command inside of a PBS batch job. The options indicate that the user wants pbsdsh to run the *myapp* program with one argument (*app-arg1*) on all four nodes allocated to the job (i.e. the default behavior).

```
#!/bin/sh
#PBS -l nodes=4
#PBS -l walltime=1:00:00

pbsdsh ./myapp app-arg1
```

8.8 Globus Support

Globus is a computational software infrastructure that integrates geographically distributed computational and information resources. Jobs are normally submitted to Globus using the utility globusrun. When Globus support is enabled for PBS, jobs can be routed between Globus and PBS. (Contact your PBS system administrator to learn if Globus support has been enabled on your PBS systems.)

8.8.1 Running Globus jobs

To submit a Globus job, users must specify the globus resource name (gatekeeper), as the following example shows:

```
% qsub -l site=globus:globus-resource-name pbsjob
%
```

The `pbs_mom_globus` daemon must be running on the same host where the `pbs_server` is running. Be sure the `pbs_server` has a `nodes` file entry *server-host*:`gl` in order for globus job status to be communicated back to the Server by `pbs_mom_globus`.

Also, be sure to create a Globus proxy certificate by running the utility `grid-proxy-init` in order to submit jobs to Globus without a password. If user's job fails to run due to an expired proxy credential or non-existent credential, then the job will be put on hold and the user will be notified of the error by email.

8.8.2 PBS and Globusrun

If you're familiar with the `globusrun` utility, the following mappings of options from PBS to an RSL string may be of use to you:

Table 10: `qsub` Options vs. Globus RSL

PBS Option	Globus RSL Mapping
`-l site=globus:<globus_gatekeeper>`	specifies the gatekeeper to contact
`-l ncpus=yy`	`count=yy`
`-A <account_name>`	`project=<account_name>`
`-l cput=yy`	`maxcputime=yy` (in minutes)
`-l pcput=yy`	`maxtime=yy` (in minutes)
`-l walltime=yy`	`maxwalltime=yy` (in minutes)
`-l mem=zz`	`maxmemory=zz` (in megabytes)

Table 10: `qsub` Options vs. Globus RSL

PBS Option	Globus RSL Mapping
`-o` <output_path>	`stdout=`<local_output_path>
`-e` <error_path>	`stderr=`<local_error_path> PBS will deliver from *local_path* to user specified output_path and stderr_path
`-v` <variable_list>	`environment=`<variable_list>`, job-type=single`

When the job gets submitted to Globus, PBS qstat will report various state changes according to the following mapping:

Table 11: PBS Job States vs. Globus States

PBS State	Globus State
TRANSIT (T)	PENDING
RUNNING (R)	ACTIVE
EXITING (E)	FAILED
EXITING (E)	DONE

8.8.3 PBS File Staging through GASS

The stagein/stageout feature of "Globus-aware" PBS works with Global Access to Secondary Storage (GASS) software. Given a stagein directive, `local-file@host:inputfile` PBS will take care of copying `inputfile` at `host` over to `localfile` at the executing Globus machine. The same process is used for a stageout directive, `localfile@host:outputfile`. PBS will take care of copying the `localfile` on the executing Globus host over to the `outputfile` at `host`. Globus mechanisms are used for transferring files to hosts that run Globus; otherwise, `pbs_scp`, `pbs_rcp` or `cp` is used. This means that if the `host` given in the argument runs Globus, then Globus communication will be opened to that system.

8.8.4 Limitation

PBS does not currently support "co-allocated" Globus jobs where two or more jobs are simultaneously run (distributed) over two or more Globus resource managers.

8.8.5 Examples

Here are some examples of using PBS with Globus:

Example 1:   If you want to run a single processor job on globus gatekeeper `mars.pbspro.com`, using whatever job manager is currently configured at that site, then you could create a PBS script like the following example:

```
% cat job.script
#PBS -l site=globus:mars.pbspro.com
echo "`hostname`:Hello world! Globus style."
```

Upon execution, this will give the sample output:

```
mars:Hello world! Globus style.
```

Example 2:   If you want to run a multi-processor job on globus gatekeeper `pluto.pbspro.com/jobmanager-fork` with cpu count set to 4, and shipping the architecture compatible executable, `mpitest` over to the Globus host `pluto` for execution, then compose a script and submit as follows:

```
% cat job.script
#PBS -l site='globus:pluto.pbspro.com:763/jobmanager-
fork:/C=US/O=Communications Package/OU=Stellar Divi-
sion/CN=shirley.com.org'
#PBS -l ncpus=4
#PBS -W stagein=mpitest@earth.pbspro.com:progs/mpitest

mpirun -n=4 ~/mpitest

wait
```

Upon execution, this sample script would produce the following output:

```
Process #2 of 4 on host: pluto at time: Mon Aug 29 17:39:01 2000
Process #3 of 4 on host: pluto at time: Mon Aug 29 17:39:01 2000
Process #1 of 4 on host: pluto at time: Mon Aug 29 17:39:01 2000
Process #0 of 4 on host: pluto at time: Mon Aug 29 17:39:01 2000
```

Example 3:   Here is a more complicated example. If you want to run a SGI-specified MPI job on a host (e.g. "sgi.galaxey.com") which is running a different batch system via the Globus gatekeeper, with a cpu count of 4, and shipping the architecture compatible executable to the Globus host, and sending the output file back to the submitting host, then do:

```
% cat job.script
#PBS -l site=globus:sgi.galaxey.com/jobmanager-lsf,
ncpus=4
#PBS -W stagein=/u/jill/mpi_sgi@earth:progs/mpi_sgi
#PBS -W stageout=mpi_sgi.out@earth:mpi_sgi.out
mpirun -np 4 /u/jill/mpi_sgi >> mpi_sgi.out
echo "Done it"
%
```

Upon execution, the sample output is:

```
Done it
```

And the output of the run would have been written to the file `mpi_sgi.out`, and returned to the user's home directory on host earth, as specified.

Note: Just like a regular PBS job, a Globus job can be deleted, signaled, held, released, rerun, have text appended to its output/error files, and be moved from one location to another.

8.9 Advance Reservation of Resources

An *Advance Reservation* is a set of resources with availability limited to a specific user (or group of users), a specific start time, and a specified duration. Advance Reservations are implemented in PBS by a user submitting a reservation with the `pbs_rsub` command. PBS will then confirm that the reservation can be met (or else reject the request). Once the scheduler has confirmed the reservation, the queue that was created to support this reser-

vation will be enabled, allowing jobs to be submitted to it. The queue will have an user level access control list set to the user who submitted the reservation and any other users the owner specified. The queue will accept jobs in the same manner as normal queues. When the reservation start time is reached, the queue will be started. Once the reservation is complete, any jobs remaining in the queue or still running will be deleted, and the reservation removed from the Server.

When a reservation is requested and confirmed, it means that a check was made to see if the reservation would conflict with currently running jobs, other confirmed reservations, and dedicated time. A reservation request that fails this check is denied by the Scheduler. If the submitter did not indicate that the submission command should wait for confirmation or rejection (-I option), he will have to periodically query the Server about the status of the reservation or wait for a mail message regarding its denial or confirmation.

8.9.1 Submitting a PBS Reservation

The **pbs_rsub** command is used to request a reservation of resources. If the request is granted, PBS provisions for the requested resources to be available for use during the specified future time interval. A queue is dynamically allocated to service a *confirmed* reservation. Users who are listed as being allowed to run jobs using the resources of this reservation will submit their jobs to this queue via the standard qsub command. (For details see "Submitting a PBS Job" on page 24.)

Although a confirmed resources reservation will accept jobs into its queue at any time, the scheduler is not allowed to schedule jobs from the queue before the reservation period arrives. Once the reservation period arrives, these jobs will begin to run but they will not in aggregate use up more resources than the reservation requested.

The pbs_rsub command returns an ID string to use in referencing the reservation and an indication of its current status. The actual specification of resources is done in the same way as it is for submission of a job. Following is a list and description of options to the pbs_rsub command.

-R datetime Specifies reservation starting time. If the reservation's end time and duration are the only times specified, this start time is calculated. The datetime argument adhers to the POSIX time specification:

[[[[CC]YY]MM]DD]hhmm[.SS]

If the day, DD, is not specified, it will default to today if the time

hhmm is in the future. Otherwise, the day will be set to tomorrow. For example, if you submit a reservation having a specification -R 1110 at 11:15am, it will be interpreted as being for 11:10am tomorrow. If the month portion, MM, is not specified, it defaults to the current month provided that the specified day DD, is in the future. Otherwise, the month will be set to next month. Similarly comments apply to the two other optional, left hand components.

-E datetime   Specifies the reservation end time. See the -R flag for a description of the datetime string. If start time and duration are the only times specified, the end time value is calculated.

-D timestring   Specifies reservation duration. Timestring can either be expressed as a total number of seconds of walltime or it can be expressed as a colon delimited timestring e.g. HH:MM:SS or MM:SS. If the start time and end time are the only times specified, this duration time is calculated.

-m mail_points   Specifies the set of events that cause the Server to send mail messages to the specified list of users. This option takes a string consisting of any combination of "a", "b","c" or "e". Default is "ac".

a	notify if the reservation is terminated for any reason
b	notify when the reservation period begins
e	notify when the reservation period ends
c	notify when the reservation is confirmed

-M mail_list   Specifies the list of users to whom the Server will attempt to send a mail message whenever the reservation transitions to one of the mail states specified in the -m option. Default: reservation's owner

-u user_list   Specifies a comma separated list of entries of the form: user@host. Entries on this list are used by the Server in conjunction with an ordered set of rules to associate a user name with the reservation.

-g group_list   Specifies a comma separated list of entries of the form:

`group@host` names. Entries on this list are used by the Server in conjunction with an ordered set of rules to associate a group name with the reservation.

-U auth_user_list   Specifies a comma separated list of entries of the form: $[+|-]$ `user@host`. These are the users who are allowed (+) or denied (-) permission to submit jobs to the queue associated with this reservation. This list becomes the `acl_users` attribute for the reservation's queue.

-G auth_group_list   Specifies is a comma separated list of entries of the form: $[+|-]$ `group@host`. Entries on this list help control the enqueuing of jobs into the reservation's queue. Jobs owned by members belonging to these groups are either allowed (+) or denied (-) entry into the queue. Any group on the list is to be interpreted in the context of the Server's host not the context of the host from which qsub was submitted. This list becomes the `acl_groups` list for the reservation's queue.

-H auth_host_list   Specifies a comma separated list of entries of the form: $[+|-]$ `hostname`. These entries help control the enqueuing of jobs into the reservation's queue by allowing (denying) jobs submitted from these hosts. This list becomes the `acl_hosts` list for the reservation's queue.

-N reservation_name
                        Declares a name for the reservation. The name specified may be up to 15 characters in length. It must consist of printable, non-white space characters with the first character alphabetic.

-l resource_list   Specifies a list of resources required for the reservation. These resources will be used for the limits on the queue that's dynamically created to service the reservation. The aggregate amount of resources for currently running jobs from this queue will not exceed these resource limits. In addition, the queue inherits the value of any resource limit set on the Server if the reservation request itself is silent about that resource.

-I seconds   Interactive mode is specified if the submitter wants to wait for an answer to the request. The pbs_rsub command will block, up to the number of seconds specified, while waiting for the scheduler to

either confirm or deny the reservation request. A negative number of seconds may be specified and is interpreted to mean: if the confirm/deny decision isn't made in the number of seconds specified, automatically delete the reservation request from the system. If automatic deletion isn't being requested and if the scheduler doesn't make a decision in the specified number of seconds, the command will return the ID string for the reservation and show the status as *unconfirmed*. The requester may periodically issue the `pbs_rstat` command with ID string as input to monitor the reservation's status.

-W other-attributes=value...

This allows a site to define any extra attribute on the reservation.

The following example shows the submission of a reservation asking for 1 node, 30 minutes of wall-clock time, and a start time of 11:30. Note that since an end time is not specified, PBS will calculate the end time based on the reservation start time and duration.

```
% pbs_rsub -l nodes=1,walltime=30:00 -R 1130
R226.south UNCONFIRMED
```

A reservation queue named "R226" was created on the local PBS Server. Note that the reservation is currently *unconfirmed*. Email will be sent to the reservation owner either confirming the reservation, or rejecting it. The owner of the reservation can submit jobs against the reservation using the `qsub` command, naming the reservation queue on the command line with the `-q` option, e.g.:

```
% qsub -q R226 aims14
299.south
```

Important: The ability to submit, query, or delete advance reservations using the `xpbs` GUI is not available in the current release.

8.9.2 Identification and Status

When the user requests an advance reservation of resources via the `pbs_rsub` command, an option ("`-I n`") is available to wait for confirmation response. The value "n" that is specified is taken as the number of seconds that the command is willing to wait. This value

can be either positive or negative. A non-negative value means that the Server/scheduler response is needed in "n or less" seconds. After that time the submitter will need to use `pbs_rstat` or some other means to descern success or failure of the request. For a negative value, the command will wait up to "-n" seconds for the request to be either confirmed or denied. If the response does not come back in "n" or fewer seconds, the Server is to automatically delete the request from the system.

8.9.3 Showing Status of PBS Reservations

The **pbs_rstat** command is used to show the status of all the reservations on the PBS Server. There are three different output formats: brief, short (default), and long. The following examples illustrate these three options.

The short option (-S) will show all the reservations in a short concise form. (This is the default display if no options are given.) The information provided is the identifier of the reservation, name of the queue that got created for the reservation, user who owns the reservation, the state, the start time, duration in seconds, and the end time.

```
% pbs_rstat -S
Name Queue User    State    Start   / Duration / End
-----------------------------------------------------------
R226 R226   james   CO   Today 11:30 / 1800 /   Today 12:00
R302 R302   barry   CO   Today 15:50 / 1800 /   Today 16:20
R304 R304   james   CO   Today 15:46 / 1800 /   Today 16:16
```

The brief option (-B) will only show the identifiers of all the reservations:

```
% pbs_rstat -B
Name: R226.south
Name: R302.south
Name: R304.south
```

The full option (-f) will print out the name of the reservation followed by all the attributes of the reservation.

```
% pbs_rstat -f R226
Name: R226.south
Reserve_Owner = james@south
reserve_type = 2
reserve_state = RESV_CONFIRMED
reserve_substate = 2
reserve_start = Fri Aug 24 11:30:00 2001
reserve_end = Fri Aug 24 12:00:00 2001
reserve_duration = 1800
queue = R226
Resource_List.ncpus = 1
Resource_List.neednodes = 1
Resource_List.nodect = 1
Resource_List.nodes = 1
Resource_List.walltime = 00:30:00
Authorized_Users = james@south
server = south
ctime = Fri Aug 24 06:30:53 2001
mtime = Fri Aug 24 06:30:53 2001
Variable_List = PBS_O_LOGNAME=james,PBS_O_HOST=south
euser = james
egroup = pbs
```

8.9.4 Delete PBS Reservations

The **pbs_rdel** command deletes reservations in the order in which their reservation identifiers are presented to the command. A reservation may be deleted by its owner, a PBS operator, or PBS Manager. Note that when a reservation is deleted, all jobs belonging to the reservation are deleted as well, regardless of whether or not they are currently running.

```
% pbs_rdel R304
```

8.9.5 Accounting

Accounting records for advance resource reservations are available in the Server's job accounting file. The format of such records closely follows the format that exists for job

records. In addition, any job that belong to an advance reservation will have the reservation ID recorded in the accounting records for the job.

8.9.6 Access Control

A site administrator can inform the Server as to those hosts, groups, and users whose advance resource reservation requests are (or are not) to be considered. The philosophy in this regard is same as that which currently exists for jobs.

In a similar vein, the user who submits the advance resource reservation request can specify to the system those other parties (user(s) or group(s)) that are authorized to submit jobs to the reservation-queue that's to be created.

When this queue is instantiated, these specifications will supply the values for the queue's user/group access control lists. Likewise, the party who submits the reservation can, if desired, control the username and group name (at the Server) that the Server associates with the reservation.

8.10 Checkpointing SGI MPI Jobs

Under Irix 6.5 and later, MPI parallel jobs as well as serial jobs can be checkpointed and restarted on SGI systems provided certain criteria are met. SGI's checkpoint system call cannot checkpoint processes that have open sockets. Therefore it is necessary to tell mpirun to not create or to close an open socket to the array services daemon used to start the parallel processes. One of two options to `mpirun` must be used:

> -cpr   This option directs mpirun to close its connection to the array services daemon when a checkpoint is to occur.
>
> -miser This option directs mpirun to directly create the parallel process rather than use the array services. This avoids opening the socket connection at all.

The `-miser` option appears the better choice as it avoids the socket in the first place.   If the `-cpr` option is used, the checkpoint will work, but will be slower because the socket connection must be closed first. Note that interactive jobs or MPMD jobs (more than one executable program) can not be checkpointed in any case. Both use sockets (and TCP/IP) to communicate, outside of the job for interactive jobs and between programs in the MPMD case.

8.11 Running PBS in a DCE Environment

PBS Pro includes optional support for DCE. (By optional, we mean that the customer may acquire a copy of PBS Pro with the standard security and authentication module replaced with the DCE module.)

There are two `-W` options available with `qsub` which will enable a `dcelogin` context to be set up for the job when it eventually executes. The use may specify either an encrypted password or a forwardable/renewable Kerberos V5 TGT.

Specify the "`-W cred=dce`" option to `qsub` if a forwardable, renewable, Kerberos V5, TGT (ticket granting ticket) with the user as the listed principal is what is to be sent with the job. If the user has an established credentials cache and a non-expired, forwardable, renewable, TGT is in the cache, that information is used.

The other choice, "`-W cred=dce:pass`", causes the `qsub` command to interact with the user to generate a DES encryption of the user's password. This encrypted password is sent to the PBS Server and MOM processes, where it is placed in a job-specific file for later use by `pbs_mom` in acquiring a DCE login context for the job. The information is destroyed when the job terminates, is deleted, or aborts.

> **Important:** The "`-W pwd=''`" option to qsub has been superseded by the above two options, and therefore should no longer be used.

Any acquired login contexts and accompanying DCE credential caches established for the job get removed on job termination or deletion.

```
% qsub -Wcred=dce <other qsub options> job-script
```

8.12 Running PBS in a Kerberos Environment

PBS Pro includes optional support for Kerberos-only (i.e. no DCE) environment. (By optional, we mean that the customer may acquire a copy of PBS Pro with the standard security and authentication module replaced with the KRB5 module.)

To use a forwardable/renewable Kerberos V5 TGT specify the "-W cred=krb5" option to `qsub`. This will cause `qsub` to check the user's credential cache for a valid forwardable/ renewable TGT which it will send to the Server and then eventually to the execution

MOM. While it's at the Server and the MOM, this TGT will be periodically refreshed until either the job finishes or the maximum refresh time on the TGT is exceeded, which ever comes first. If the maximum refresh time on the TGT is exceeded, no KRB5 services will be available to the job, even though it will continue to run.

Chapter 9

Running Multi-node Jobs

If PBS has been set up to manage a cluster of computers or on a parallel system, it is likely with the intent of managing multi-node parallel jobs. PBS can allocate individual nodes to multiple jobs at the same time (called *time-sharing*) or to a single job at a time (providing *exclusive access*; also called *space-sharing*). When a job requests exclusive access, the entire node is allocated to the job regardless of the number of processors or the amount of memory in the node. Users should explicitly request such exclusive access if desired. To have PBS allocate nodes to a user's job, the user must specify how many nodes and of what type are required for the job. The user's parallel job must then execute tasks on the allocated nodes. The chapter explains how to submit such multi-node parallel jobs to PBS.

> **Important:** Recall that the previously discussed "`resc_spec`" requests are for single-node jobs, and are *not* supported for multi-node jobs. (See also section 4.10 "Single-Node Conditional Requests" on page 43.)

9.1 Node Specification Syntax

The nodes `resources_list` item is set by the user (via the `qsub` command) to declare the node requirements for the job. It is a string of the form

```
-l nodes=node_spec[+node_spec...][#suffix]
```

where *node_spec* can be any of the following:

N	Number of nodes needed; if number is used, it must be listed first
nodename	Host name of the specific node requested
property[:property...]	One or more site-specific node properties
ppn=X	The number of processes (tasks) per node (defaults to 1)
cpp=Y	The number of CPUs (threads) per process (defaults to 1)
N:spec[:spec]	Number of nodes, followed by any of the above requests, which may be further followed by additional of the above requests.

The 'node specification' value is one or more `node_spec` joined with the '+' character. Each `node_spec` represents one or more nodes at run time. If no number is specified, one (1) is assumed. The total number of (virtual) processors allocated per node is the product of the number of processes per node (`ppn`) times the number of CPUs per process (`cpp`).

The `node_spec` may be followed by one or more *global modifiers* (see the `#suffix` in the syntax line above). These are special flags which apply to every `node_spec` in the entire specification. Any site-defined property may be used as global modifiers, as well as the two pre-defined modifiers: "`#shared`" (requesting shared access to a node) and "`#excl`" (requesting exclusive access to the entire node, regardless of the number of CPUs requested).

The "`#shared`" modifier is used when you are willing to share your nodes with other jobs. This typically results in less wait in the queue, but the individual runtime of the job may be longer.

The "`#excl`" modifier is used to request exclusive access the nodes, regardless of the number of CPUs on the nodes. No other job will be allocated those nodes while your jobs is running on them. This typically results in longer queue wait times, but faster runtime for the individual application. Exclusive access will not be granted to time-shared nodes.

Important:	The keywords `shared` and `excl` only apply when used as global modifiers.

9.2 Job-specific Nodes File

PBS provides the names of the all the nodes allocated to a particular job in a job-specific file in the directory `/usr/spool/PBS/aux/`. The file is owned by root but is world readable. The full path and name of the file is passed to the job in the environment variable `PBS_NODEFILE`. For IBM SP systems, it is also in the variable `MP_HOSTFILE`. The order that the nodes are listed in the `PBS_NODEFILE` depends on the `node_spec` request. This is further illustrated in the Examples section below.

9.3 Examples

This section contains several examples for using the various options of the node specification syntax.

9.3.1 Basic `node_spec` Usage

A simple `node_spec` requests a specific number of nodes. This is the most common case for single- and dual-processor Linux clusters, where all the nodes are identical. It doesn't matter to your job which nodes are allocated to it. Thus requesting simply the number of nodes needed is sufficient. The following examples each request eight nodes.

```
% qsub -l nodes=8 mysubrun
```

```
#!/bin/sh
#PBS -l nodes=8
...
```

9.3.2 Requesting Multiple Processes Per Node

A user may request to run multiple processes per node by adding the terms `ppn=#` (for processes per node) to each node expression. As a simple case, consider:

```
#!/bin/sh
#PBS -l nodes=1:ppn=3
...
```

which requests to run three processes on a single node. One node would be allocated to the job, as would three virtual processors on that node. Furthermore, the allocated node will be listed in the `PBS_NODEFILE` three times (one per line).

The following example request two virtual processors on each of three nodes, and the PBS_NODEFILE would contain the names of the three allocated nodes, each listed twice, as such: A, B, C, A, B, C.

```
#!/bin/sh
#PBS -l nodes=3:ppn=2
...
```

A more elaborate (and possibly contrived) example would be the following, which requests two virtual processors on one node plus an additional four virtual processors on a second node. (The PBS_NODEFILE would contain the two node names multiple times, in the following order: A, B, A, B, B, B).

```
#!/bin/sh
#PBS -l nodes=1:ppn=2+1:ppn=4
...
```

This allows a user to request varying numbers of processes on nodes and by setting the number of *NPROC* on the mpirun command to the total number of allocated nodes, run one process on each node. (This is useful if one set of files have to be created on each node by a setup process regardless of the number of processes that will run on the nodes during the computation phase.)

9.3.3 Processes (Tasks) vs CPUs

It is further possible to specify the number of CPU (threads) per process, using the cpp=# modifier. For example, the node specification:

```
#!/bin/sh
#PBS -l nodes=4:ppn=3:cpp=2
...
```

requests a total of four separate nodes; three parallel processes (tasks) should be run on each node (This means each node will appear in the PBS_NODEFILE three times.); and two CPUs should be allocated to each process so that each process can run two threads (which results in the OMP_NUM_THREADS and NCPUS environment variables to be set to two). The above specification yields (4 nodes * 3 processes * 2 CPUs), for a total 24 CPUs.

9.3.4 Order of Nodes in `PBS_NODEFILE`

If the job only requests one process per node the order of the nodes will match the order requested. However, if multiple processes are placed per node, the file will contain each separate node first, listed in order to match the request, followed by the required number of repeating occurrences of each node. For example, if a user requests the following nodes:

```
#!/bin/sh
#PBS -l nodes=1:ppn=3+1:ppn=2+1:ppn=1
...
```

then the `PBS_NODEFILE` will contain: A, B, C, A, B, A. This allows the user to have a parallel job step that runs only one process on each node, (e.g. by setting `-nproc=3`). This is useful if the job requires files to setup, one per node, on each node before the main computation is preformed.

If a user specifies `-l nodes=1:ppn=3:cpp=2` then node A will be listed 3 times and the environment variables *OMP_NUM_THREADS* and *NCPUS* will both be set to 2.

If the user specifies `-l nodes=1:ncpus=2` then node A will be listed in the `PBS_NODEFILE` once, and the environment variables *OMP_NUM_THREADS* and *NCPUS* will both be set to 2. Which method is used depends on the individual application, and how the user wants the processes to be distributed across the nodes allocated to the job.

9.3.5 Interaction of `nodes` vs `ncpus`

If a job is submitted to PBS with a `nodes` resource specification (`-l nodes=X`) and without an `ncpus` specification (no `-l ncpus=y`), then PBS will set the `ncpus` resource to match the number of CPUs required by the `nodes` specification.

The following relates what happens if a job is submitted with a combination of `-l ncpus=value` and `-l nodes=value`

The variable X is used to indicate any integer larger than 1; Y and Z can be any legal integer. The variable N is any integer equal to or greater than 1.

Given "`-l ncpus=N -l nodes=value`", if "*value*" is:

1	Then ok and then nodes value is equivalent to `1:ncpus=`N
Xi[+Xj..]	Then let X = sum(Xi+Xj+...)
	The value of `ncpus` must be a multiple of the number of nodes: if N%X == 0, then `ncpus=`N and the `nodes` value becomes X:cpp=(N/X)
	That is N/X cpus per node
	If N%X != 0, then this is an error

If "*value*" includes "ppn" and does not include "cpp", then the results are the same as in the above case; #cpp=N/(number of tasks)

For any other case, X:ppn=Y:cpp=Z, a default N value is replaced by sum of X*Y*Z across the node spec. E.g. `-l  nodes=2:blue:ppn=2:cpp=3+3` is 15 cpus, so `ncpus` is reset to 15. A non-default `ncpus` value is an error when `cpp=` is specified in the node specification. Here are a few more examples:

> `-lncpus=6 -lnodes=3:blue+3:red` is correct
> `-lncpus=12 -lnodes=3:blue+3:red` is also correct

but

> `-lncpus=10  -lnodes=3:blue+3:red` is not because 10 CPUs cannot be spread evenly across 6 nodes.

A job that does not have a node specification (resource requirement) but does specify a number of CPUs via the `-l  ncpus=#` syntax is allocated processors as if the job did have a node specification of the form:

> `-l nodes=1:cpp=#`

9.4 Summary of Node Specification Options

Table 12: Node Specification Options

Desired Node/ CPU/ Process Layout	Node Specification Option to *qsub*	Resulting *PBS_ NODEFILE*	Resulting Value of *NCPUS* Variable
1 CPU anywhere	`-l ncpus=1`	S	1
1 entire node	`-l nodes=1`	A	1
4 entire nodes	`-l nodes=4`	ABCD	1
3 CPUs on 1 node	`-l nodes=1:ppn=3`	AAA	3
3 CPUs on each of 4 nodes with 2 CPUs allocated per process	`-l nodes=4:ppn=3:cpp=2`	ABCDAB-CDABCD	2
2 nodes with 2 virtual processors per node	`-l nodes=1:ppn=2+1:ppn=2`	ABAB	2, 2
1 node with 2 virtual processors plus 1 node with 3 virtual processors	`-l nodes=1:ppn=2+1:ppn=3`	ABABB	2, 3

9.4.1 Time-shared vs Cluster Nodes

The difference between time-shared and cluster nodes is:

1. Time-share nodes may not be requested exclusively with the `#excl` suffix.
2. More processes than CPUs can be run on time-shared nodes but not on cluster nodes.
3. Allocation of cluster nodes remains based on the number of (virtual) processors.

9.5 MPI Jobs with PBS

On a typical system, to execute a Message Passing Interface (MPI) program you would use the `mpirun` command. For example, here is a sample PBS script for a MPI job:

```
#!/bin/sh
#PBS -l nodes=32
#
mpirun -np 32 -machinefile $PBS_NODEFILE ./a.out
```

Or, when using a version of MPI that is integrated with PBS:

```
#!/bin/sh
#PBS -l nodes=32
#
mpirun -np 32 ./a.out
```

9.6 PVM Jobs with PBS

On a typical system, to execute a Parallel Virtual Machine (PVM) program you would use the `pvmexec` command. For example, here is a sample PBS script for a PVM job:

```
#!/bin/sh
#PBS -l nodes=32
#
pvmexec ./a.out -inputfile datain
```

9.7 OpenMP Jobs with PBS

To provide support for OpenMP jobs, the environment variable `OMP_NUM_THREADS` is created for the job with the value of the number of CPUs allocated to the job. The variable `NCPUS` is also set to this value.

Appendix A: PBS Environment Variables

Table 13: PBS Environment Variables

Variable	Meaning
ENVIRONMENT	Indicates if job is a batch job, or a PBS interactive job.
NCPUS	Number of threads (or cpus per process (cpp)) on the node
OM_NUM_THREADS	Same as NCPUS.
PBS_ENVIRONMENT	Same as ENVIRONMENT.
PBS_JOBCOOKIE	Unique identifier for inter-MOM job-based communication.
PBS_JOBID	The job identifier assigned to the job by the batch system.
PBS_JOBNAME	The job name supplied by the user.
PBS_MOMPORT	Port number on which this job's MOMs will communicate.
PBS_NODEFILE	The filename containing a list of nodes assigned to the job.
PBS_NODENUM	Logical node number of this node allocated to the job.
PBS_O_HOME	Value of **HOME** from submission environment.
PBS_O_HOST	The host name on which the qsub command was executed.
PBS_O_LANG	Value of **LANG** from submission environment
PBS_O_LOGNAME	Value of **LOGNAME** from submission environment
PBS_O_MAIL	Value of **MAIL** from submission environment
PBS_O_PATH	Value of **PATH** from submission environment
PBS_O_QUEUE	The original queue name to which the job was submitted.
PBS_O_SHELL	Value of **SHELL** from submission environment
PBS_O_SYSTEM	The operating system name where qsub was executed.

Table 13: PBS Environment Variables

Variable	Meaning
PBS_O_TZ	Value of **TZ** from submission environment
PBS_O_WORKDIR	The absolute path of directory where qsub was executed.
PBS_QUEUE	The name of the queue from which the job is executed.
PBS_TASKNUM	The task (process) number for the job on this node.
TMPDIR	The job-specific temporary directory for this job.

Appendix B: Converting From NQS to PBS

For those converting to PBS from NQS or NQE, PBS includes a utility called **nqs2pbs** which converts an existing NQS job script so that it will work with PBS. (In fact, the resulting script will be valid to both NQS and PBS.) The existing script is copied and PBS directives ("#PBS") are inserted prior to each NQS directive (either "#QSUB" or "#Q$") in the original script.

```
% nqs2pbs existing-NQS-script new-PBS-script
%
```

Important: Converting NQS date specifications to the PBS form may result in a warning message and an incomplete converted date. PBS does not support date specifications of "today", "tomorrow", or the name of the days of the week such as "Monday". If any of these are encountered in a script, the PBS specification will contain only the time portion of the NQS specification (i.e. #PBS -a hhmm[.ss]). It is suggested that you specify the execution time on the qsub command line rather than in the script. All times are taken as local time. If any unrecognizable NQS directives are encountered, an error message is displayed. The new PBS script will be deleted if any errors occur.

Section "Setting Up Your UNIX/Linux Environment" on page 18 discusses PBS environment variables. For NQS compatibility, the variable **ENVIRONMENT** is provided, set to the same value as **PBS_ENVIRONMENT**.

A queue complex in NQS was a grouping of queues within a batch Server. The purpose of a complex was to provide additional control over resource usage. The advanced scheduling features of PBS eliminates the requirement for queue complexes.
