

## G13CBF – NAG Fortran Library Routine Document

**Note.** Before using this routine, please read the Users' Note for your implementation to check the interpretation of bold italicised terms and other implementation-dependent details.

### 1 Purpose

G13CBF calculates the smoothed sample spectrum of a univariate time series using spectral smoothing by the trapezium frequency (Daniell) window.

### 2 Specification

```

SUBROUTINE G13CBF(NX, MTX, PX, MW, PW, L, KC, LG, XG, NG, STATS,
1              IFAIL)
  INTEGER      NX, MTX, MW, L, KC, LG, NG, IFAIL
  real       PX, PW, XG(KC), STATS(4)

```

### 3 Description

The supplied time series may be mean or trend corrected (by least-squares), and tapered, the tapering factors being those of the split cosine bell:

$$\begin{aligned} & \frac{1}{2} \left( 1 - \cos \left( \frac{\pi(t-\frac{1}{2})}{T} \right) \right), & 1 \leq t \leq T \\ & \frac{1}{2} \left( 1 - \cos \left( \frac{\pi(n-t+\frac{1}{2})}{T} \right) \right), & n+1-T \leq t \leq n \\ & 1, & \text{otherwise} \end{aligned}$$

where  $T = \lfloor \frac{np}{2} \rfloor$  and  $p$  is the tapering proportion.

The unsmoothed sample spectrum

$$f^*(\omega) = \frac{1}{2\pi} \left| \sum_{t=1}^n x_t \exp(i\omega t) \right|^2$$

is then calculated for frequency values

$$\omega_k = \frac{2\pi k}{K}, \quad k = 0, 1, \dots, [K/2]$$

where  $[ ]$  denotes the integer part.

The smoothed spectrum is returned as a subset of these frequencies for which  $k$  is a multiple of a chosen value  $r$ , i.e.,

$$\omega_{r,l} = \nu_l = \frac{2\pi l}{L}, \quad l = 0, 1, \dots, [L/2]$$

where  $K = r \times L$ . The user will normally fix  $L$  first, then choose  $r$  so that  $K$  is sufficiently large to provide an adequate representation for the unsmoothed spectrum, i.e.,  $K \geq 2 \times n$ . It is possible to take  $L = K$ , i.e.,  $r = 1$ .

The smoothing is defined by a trapezium window whose shape is supplied by the function

$$\begin{aligned} W(\alpha) &= 1, & |\alpha| \leq p \\ W(\alpha) &= \frac{1-|\alpha|}{1-p}, & p < |\alpha| \leq 1 \end{aligned}$$

the proportion  $p$  being supplied by the user.

The width of the window is fixed as  $2\pi/M$  by the user supplying  $M$ . A set of averaging weights are constructed:

$$W_k = g \times W \left( \frac{\omega_k M}{\pi} \right), \quad 0 \leq \omega_k \leq \frac{\pi}{M}$$

where  $g$  is a normalising constant, and the smoothed spectrum obtained is

$$\hat{f}(\nu_l) = \sum_{|\omega_k| < \frac{\pi}{M}} W_k f^*(\nu_l + \omega_k).$$

If no smoothing is required  $M$  should be set to  $n$ , in which case the values returned are  $\hat{f}(\nu_l) = f^*(\nu_l)$ . Otherwise, in order that the smoothing approximates well to an integration, it is essential that  $K \gg M$ , and preferable, but not essential, that  $K$  be a multiple of  $M$ . A choice of  $L > M$  would normally be required to supply an adequate description of the smoothed spectrum. Typical choices of  $L \simeq n$  and  $K \simeq 4n$  should be adequate for usual smoothing situations when  $M < n/5$ .

The sampling distribution of  $\hat{f}(\omega)$  is approximately that of a scaled  $\chi_d^2$  variate, whose degrees of freedom  $d$  is provided by the routine, together with multiplying limits  $mu$ ,  $ml$  from which approximate 95% confidence intervals for the true spectrum  $f(\omega)$  may be constructed as  $[ml \times \hat{f}(\omega), mu \times \hat{f}(\omega)]$ . Alternatively,  $\log \hat{f}(\omega)$  may be returned, with additive limits.

The bandwidth  $b$  of the corresponding smoothing window in the frequency domain is also provided. Spectrum estimates separated by (angular) frequencies much greater than  $b$  may be assumed to be independent.

## 5 Parameters

- 1: NX — INTEGER *Input*  
*On entry:* the length of the time series,  $n$ .  
*Constraint:*  $NX \geq 1$ .
- 2: MTX — INTEGER *Input*  
*On entry:* whether the data are to be initially mean or trend corrected.  
MTX = 0 for no correction,  
MTX = 1 for mean correction,  
MTX = 2 for trend correction.  
*Constraint:*  $0 \leq MTX \leq 2$ .
- 3: PX — *real* *Input*  
*On entry:* the proportion of the data (totalled over both ends) to be initially tapered by the split cosine bell taper. (A value of 0.0 implies no tapering).  
*Constraint:*  $0.0 \leq PX \leq 1.0$ .
- 4: MW — INTEGER *Input*  
*On entry:* the value of  $M$  which determines the frequency width of the smoothing window as  $2\pi/M$ . A value of  $n$  implies no smoothing is to be carried out.  
*Constraint:*  $1 \leq MW \leq NX$ .
- 5: PW — *real* *Input*  
*On entry:* the shape parameter,  $p$ , of the trapezium frequency window.  
A value of 0.0 gives a triangular window, and a value of 1.0 a rectangular window.  
If  $MW = NX$  (i.e., no smoothing is carried out), then PW is not used.  
*Constraint:*  $0.0 \leq PW \leq 1.0$ .

- 6:** L — INTEGER *Input*  
*On entry:* the frequency division,  $L$ , of smoothed spectral estimates as  $2\pi/L$ .  
*Constraints:*  $L \geq 1$ ,  
 L must be a factor of KC (see below).
- 7:** KC — INTEGER *Input*  
*On entry:* the order of the fast Fourier transform (FFT),  $K$ , used to calculate the spectral estimates. KC should be a multiple of small primes such as  $2^m$  where  $m$  is the smallest integer such that  $2^m \geq 2n$ , provided  $m \leq 20$ .  
*Constraints:*  
 $KC \geq 2 \times NX$ ,  
 KC must be a multiple of L. The largest prime factor of KC must not exceed 19, and the total number of prime factors of KC, counting repetitions, must not exceed 20. These two restrictions are imposed by C06EAF which performs the FFT.
- 8:** LG — INTEGER *Input*  
*On entry:* indicates whether unlogged or logged spectral estimates and confidence limits are required.  
 LG = 0 for unlogged.  
 LG  $\neq$  0 for logged.
- 9:** XG(KC) — *real* array *Input/Output*  
*On entry:* the  $n$  data points.  
*On exit:* contains the NG spectral estimates  $\hat{f}(\omega_i)$ , for  $i = 0, 1, \dots, [L/2]$ , in XG(1) to XG(NG) (logged if LG  $\neq$  0). The elements XG( $i$ ), for  $i = NG + 1, \dots, KC$  contain 0.0.
- 10:** NG — INTEGER *Output*  
*On exit:* the number of spectral estimates,  $[L/2] + 1$ , in XG.
- 11:** STATS(4) — *real* array *Output*  
*On exit:* four associated statistics. These are the degrees of freedom in STATS(1), the lower and upper 95% confidence limit factors in STATS(2) and STATS(3) respectively (logged if LG  $\neq$  0), and the bandwidth in STATS(4).
- 12:** IFAIL — INTEGER *Input/Output*  
*On entry:* IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to Chapter P01 for details.  
*On exit:* IFAIL = 0 unless the routine detects an error or gives a warning (see Section 6).  
**For this routine**, because the values of output parameters may be useful even if IFAIL  $\neq$  0 on exit, users are recommended to set IFAIL to -1 before entry. **It is then essential to test the value of IFAIL on exit.** To suppress the output of an error message when soft failure occurs, set IFAIL to 1.

## 6 Error Indicators and Warnings

Errors or warnings specified by the routine:

IFAIL = 1

On entry, NX < 1,  
 or MTX < 0,  
 or MTX > 2,  
 or PX < 0.0,  
 or PX > 1.0,  
 or MW < 1,  
 or MW > NX,  
 or PW < 0.0 and MW ≠ NX,  
 or PW > 1.0 and MW ≠ NX,  
 or L < 1.

IFAIL = 2

On entry, KC < 2 × NX,  
 or KC is not a multiple of L,  
 or KC has a prime factor exceeding 19,  
 or KC has more than 20 prime factors, counting repetitions.

IFAIL = 3

This indicates that a serious error has occurred. Check all array subscripts and subroutine parameter lists in calls to G13CBF. Seek expert help.

IFAIL = 4

One or more spectral estimates are negative. Unlogged spectral estimates are returned in XG, and the degrees of freedom, unlogged confidence limit factors and bandwidth in STATS.

IFAIL = 5

The calculation of confidence limit factors has failed. This error will not normally occur. Spectral estimates (logged if requested) are returned in XG, and degrees of freedom and bandwidth in STATS.

## 7 Accuracy

The FFT is a numerically stable process, and any errors introduced during the computation will normally be insignificant compared with uncertainty in the data.

## 8 Further Comments

G13CBF carries out a FFT of length KC to calculate the sample spectrum. The time taken by the routine for this is approximately proportional to  $KC \times \log(KC)$  (but see Section 8 of the document for C06EAF for further details).

## 9 Example

The example program reads a time series of length 131. It selects the mean correction option, a tapering proportion of 0.2, the option of no smoothing and a frequency division for logged spectral estimates of  $2\pi/100$ . It then calls G13CBF to calculate the univariate spectrum and prints the logged spectrum together with 95% confidence limits. The program then selects a smoothing window with frequency width  $2\pi/30$  and shape parameter 0.5 and recalculates and prints the logged spectrum and 95% confidence limits.

## 9.1 Program Text

**Note.** The listing of the example program presented below uses bold italicised terms to denote precision-dependent details. Please read the Users' Note for your implementation to check the interpretation of these terms. As explained in the Essential Introduction to this manual, the results produced may not be identical for all implementations.
